It at once occurred to him that if instead of *indentation representing Morse characters*, he could obtain indentations made by vibrations representing articulate speech, the machine would reproduce the spoken words. It was but the work of an hour for such a genius to make a little alteration upon that machine. He substituted for the telegraph recording apparatus a diaphragm with an indenting needle, and, with this addition the machine was used as a test for the idea of a phonograph. This test proved the correctness of his inventive judgment.

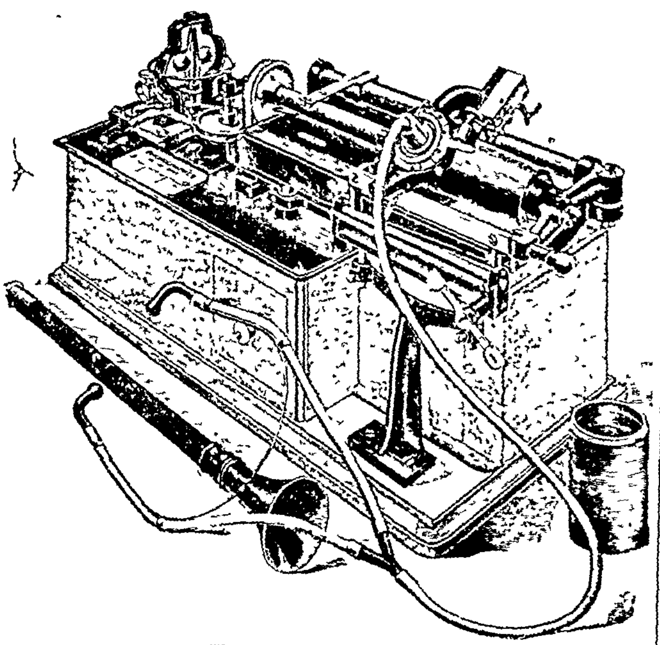
Following closely on the heels of this experiment, a phonograph was constructed on a plan more favorable for attaching a diaphragm, and tin foil for receiving the indentations was substituted for paper. It was then *exhibited for the first time* outside of Mr. Edison's laboratory at the office of the Scientific American and several different exhibits. One was then presented to the South Kensington Museum of London and the Academy of Sciences of Paris. It was a curious spectacle in witnessing the expression of the faces of the academicians when his agent, M. Puskas, caused the wonderful instrument to speak. A murmur of admiration was heard from all parts of the hall—a murmur succeeded by repeated applause. The learned Academy, generally so cold, has never before abandoned *itself* to such enthusiasm. Yet some members of a skeptical turn of mind, instead of examining the physical fact, ascribed it to moral causes, and a report soon ran through the room which seemed to accuse the Academy of having been mystified by a clever ventriloquist. Certainly the spirit of Ancient Gaul is still to be found among the French, even in the Academy. One said that the sounds emitted by the instrument were precisely those of a ventriloquist. Another asked if M. Puskas, face and lips as he turned the instrument did not resemble the grimaces of a ventriloquist. A third admitted that the phonograph might emit sounds, but believed it was much helped by the manipulator. Finally the Academy requested M. du Moncel to try the experiment, and as he was not accustomed to speak into the instrument it was unsuccessful, to the great joy of the incredulous. Some members of the Academy, however, desirous of ascertaining the real nature of the effects, begged M. Puskas to repeat the experiment before them again under such conditions as they laid down for him. M. Puskas complied with this request, and they were absolutely satisfied with the result. Yet others still remained incredulous, and it was necessary that they should make the experiments themselves before they accepted the fact that speech could be reproduced in so simple a way.

The anecdote I have just related cannot be interpreted to the discredit of the Académie des Sciences, since it is especially bound to preserve the true principles of science intact, and only to accept startling facts *after* a careful examination. Owing to this attitude, all which emanated from the Academy can be received with complete confidence; and we cannot approve *too highly of* reserve which does not give way to the first impulse of enthusiasm and admiration.

If this invention had taken place in the middle ages it would certainly have been applied to ghostly apparitions, and it would have been invaluable to miracle-mongers.

We have all read much about this wonderful invention and the world at large still awaits the further growth of that child.

The latest types of the phonograph and the Bettini micro-phonograph which forms the subject of this demonstration and paper are of the most improved patterns. Though the micro-phonograph has not had its exhibits as yet, with one exception, and that one was before the New York Medical Association, in April 1881, where I had the honor to first practically demonstrate this machine and show how as an assistant to medical and other sciences it might be applied.

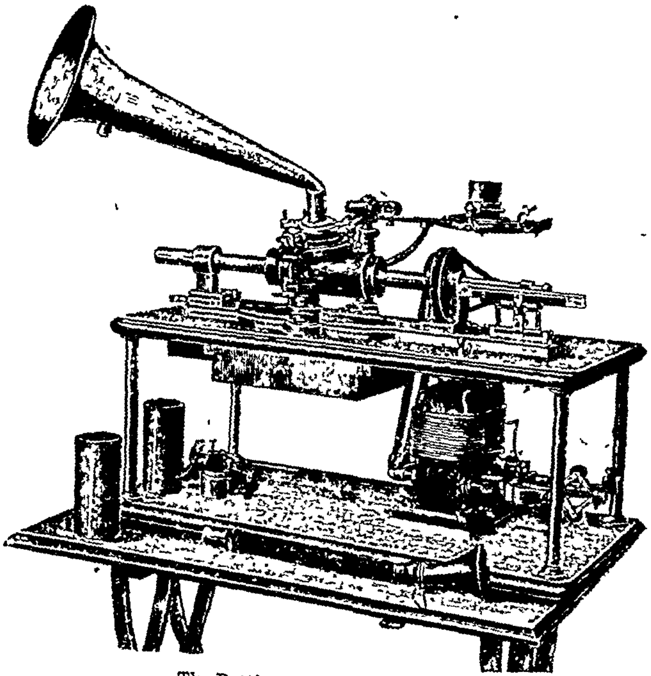


The Edison Phonograph.

Here it would be well to give by way of explanation the principles underlying the phonograph in order that those of our profession not thoroughly versed in the scientific points of the phonograph and the micro-phonograph may grasp those details I propose to give. Note that when a stroke is given a bell, the blow sets the particles of metal in vibrations. These vibrations are communicated to the surrounding atmosphere, which being an elastic medium, conveys the impulses to the ear, and waves of sound pulses roll in very much as the waves come rolling in toward the shore down by the sea. The speed at which the sound travels is 1,093 feet per second at the temperature of freezing water, and as the temperature rises the speed increases about one foot to every degree.

Every human being has in his or her throat a delicate membrane which, when he or she speaks, is set in vibration, and in turn sends the vibratory impulses from the throat and mouth, and they impinge upon the drum of the ear. This membrane vibrates at different rates in different persons. For instance, in the soprano of women it is exceedingly rapid, while the bass of male singers is much slower. From this we find that the pitch of woman's voice is far higher, as a rule, than that of a man. The pitch of a tone depends upon the number of vibrations in a second, and upon nothing else, therefore if a tone is produced with double the number of vibrations of another, it is said to be an octave higher. Now, when we speak with the mouthpiece of the phonograph or the micro-phonograph transmitter, the sound pulses impinge upon the glass diaphragm of the phonograph and upon the metal diaphragm of the micro-phonograph, which causes the needle attached thereto (*phonograph*), *and the spider attachment to the diaphragm* of the micro-phonograph, to indent the composition wax cylinder as it traces over the surface, the depth, length and general character of the sound pulses. When the tone is loud and full, they are deep, and when the pitch of the tone is high the indentations are close together. The recorders are those parts of either of the machines that hold the diaphragms, and in the phonograph the recorder is turned to the right, bringing the reproducing needle thereon mounted into play, which, as it traverses the track made by the broader needle, slips in and out of the indentations therein, and in so doing moves the reproducing diaphragm on the phonograph with it, and thus by mechanically imitating the motions of the diaphragm in one's own throat, reproduces all that was spoken in loud, middle or low tones, sung in different registers, modulated tones as used by the actor or elocutionist, and in many other phases of reproduction too numerous to cite here.

The micro-phonograph thus far has been only alluded to. An illustration is given below in two cuts, representing one of the cardinal features of a new phonograph. This is the invention of Lieut. Gianni Bettini. It is of marvelous power and perfection, and stamps its inventor as a man of surpassing mechanical genius.



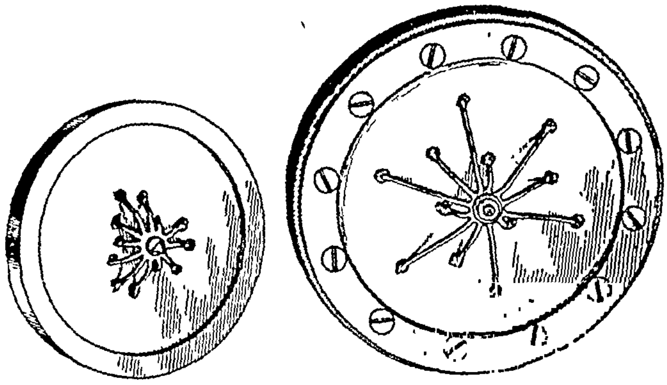
The Bettina Micro-Phonograph.

As an actual acoustical achievement in the recording and reproduction of both vocal and instrumental effects, it defies description in words. It can only be appreciated by listening to its performance.

This phonograph is peculiar in form and construction of its diaphragm and the novel and philosophical method of attaching to its surface the central needle-point, which also produces its indentations in the rotating cylinder of wax while the diaphragm vibrates over it by the action of vocal words or instrumental sounds. Let me briefly explain this Bettini new diaphragm.

Instead of attaching the needle-point directly and firmly to the center of the diaphragm as heretofore done, Lieut. Bettini uses what he calls a "*spider*," which is a little frame having several radial legs, the feet of which bear against the diaphragm at a number of points surrounding the center, and at different distances from it.

The object of this "spider" with its radial bearings is to carry out the inventor's discovery that this tensioned diaphragm does not vibrate as a whole, as has been supposed, and as it would have to do under the action of air waves, according to the teaching of modern science; but on the contrary, that it vibrates in numerous small divisions or sectors which may happen to be in unisonant or tensioned sympathy with the vibrating organs of the voice or of other tones directed against the diaphragm. Thus should the center of the diaphragm, for example, happen to be a note or a silent point not in sympathy with a certain pitch of tone, some small sector might prove to be in exact sympathy, and would thus cause the needle, through one of the spider legs, to respond, and in this way not only would the whole diaphragm be utilized, making the reproduced tone many times louder than by a single point of central contact, but would secure much greater variety of the timbre, or *clang tint* of voice, as also a record of a much greater number of voices and musical instruments than could possibly occur with a single point of contact with the diaphragm's center. (See these spider leg bearings in cut.)



Recorder Reproducer
Of Lieut. Bettini's Micro-Phonograph.

Although the Edison phonograph, with its single central bearing and needle-point, does actually record and reproduce accurately the spoken sounds and timbre of the voice, as also the sounds of a number of musical instruments played at the same time, it is a fact which you will observe at once, that its achievement in the complexity of articulate speech, in the inspiratory and respiratory sounds, either of the normal or abnormal, in the delicate fineness of any vocal expression, in the volume of tone and in the number of voices and instruments capable of being recorded at the same time, it is said by scientists that it bears not as good a comparison—due alone, as believed, to this method of utilizing the sympathetic sectors of the vibrating diaphragm.

Now if the inventor could actually determine beforehand every division and subdivision of the vibrating diaphragm constituting a sector which would act in sympathy with every pitch of tone employed in vocal speech and instrumental music, and could he then adjust a "spider" leg to each without unduly stiffening the diaphragm, the number of instruments and voices he could record and reproduce would be almost unlimited. Having no means, however, of thus determining in advance these various sympathetic sectors, he had simply to guess it, and attach his spider by as many points of bearing as he deemed prudent, the result of which has astonished himself no less than it has astonished all who thus far have heard the micro-phonograph. From the triumphs already attained by contact of the needle supports with only a few sectors of the diaphragm, there can be no doubt but many other sectors will yet be found and connected with the needle by additional "spider" legs, to bring the micro-phonograph to still greater perfection.

[1] Now with all the wonderful genius displayed by this inventor in utilizing the different sectors of the diaphragm, it is only fair to say that he has failed to give a scientific and philosophical explanation, satisfactory to himself, as to how it is possible for *this single needle-point, in retracing this single line* indentations in the wax cylinder, to reproduce all the marvelous acoustical effects of twenty or more voices and instruments in their complexity of pitch, intensity, quality, expression, etc. This he frankly admits he has been unable to do.

While the diaphragm, as we can now understand and as M. Bettini discovered, is originally acted upon and thus acts upon the needle by all the voices and instruments being directed against its different vibrational sectors corresponding in tension with the pitch, timbre, intensity, etc., of such individual tones, it is by no means such an easy matter to imagine or discover the true philosophical explanation as to how this same single, delicate needle point, in being again rubbed over this line of indentations, will reproduce loudly and accurately all the tones of a score of voices and instruments. And while it is no disparagement to the great inventor to say that he fails to solve this mystery of mysteries in acoustical science, it is but just to history here to place on record the fact that one writer alone of all contemporaneous scientific and philosophical investigators, has been able to accomplish this task. I here refer to Dr. Wilford Hall.

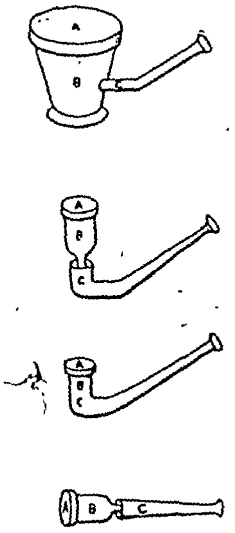
Mr. Robert Rogers, in speaking of the philosophical and scientific explanation of Dr. Hall's discovery regarding the phonograph, says: "Nearly two years ago, in the May number of *The Microcosm* (1880), under the head of 'Voice Pictures,' Dr. Hall printed a leading editorial by which he undertook a task he had contemplated for several years, of explaining the action of the phonograph, and also at the same time to account for the 'voice pictures' of Mr. Hughes, then creating a scientific sensation throughout the civilized world. It was this very problem of the hitherto inexplicable results of the needle-point reproducing spoken words by retracing its line of indentations in the wax cylinder, which Dr. Hall had the ingenuity to attack. And most remarkable to record, as an introduction to that unprecedented solution, he described in minute detail the very subdivisions of the phonograph-diaphragm into its small sympathetic sectors which must respond to the pitch, precisely as Lieut. Bettini was at that time mechanically working out!"

---

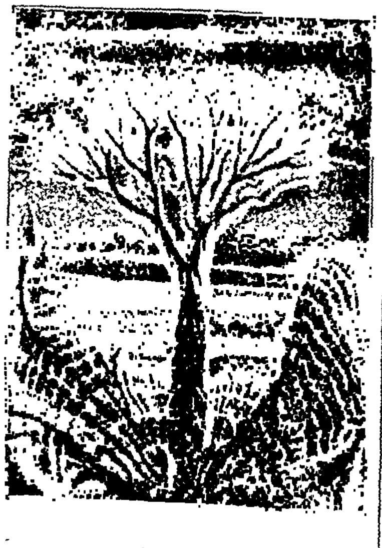
[1] The Microcosm, Vol. ix, February, 1892, Dr. Wilford Hall's explanation of scientific forecast.

"A more remarkable case of determining intricate, mechanical and scientific results by pure philosophical ratiocination, which could only be known surely by experimental tests, does not probably exist in the records of physical research, not even excepting the discovery of Neptune by the great French astronomer, Le Venier. Indeed, the location and discovery of Neptune were based upon clearly observed movements of other planets, while there was neither a movement nor an indentation within sight under the most powerful microscope, to indicate to Dr. Hall the ground on which his magnificent physical discovery was based."

"In Vol. 7 of the *Microcosm*, under the title of 'Voice Pictures,' is found not only the foreshadowing of the true mechanical action of the phonograph-diaphragm in the subdivisions of its surface into small nodes and sympathetic sections as practically demonstrated by Lieut. Bettini, but there will be seen in detail the only possible explanation of the muliform and multifold work of a single needlepoint—an explanation which has defied all previous attempts, and which M. Bettini declares he had not been able to discover, even after his experimental demonstration of the same.



The Eidophone.

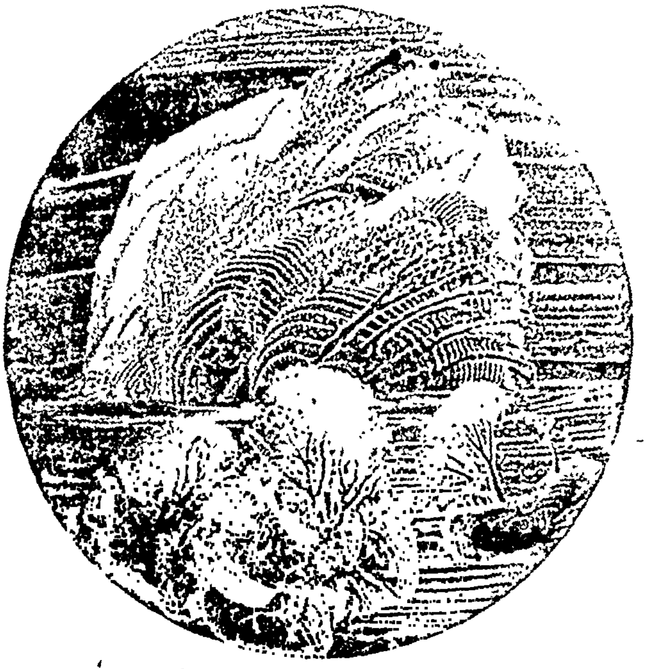


Tree Form.

In order to give my hearers and readers of this article an idea of this notable case of foreshadowing by scientific ratiocination alone, a philosophical result which could only be determined by experiment, I append here a few remarks from Dr. Hall's masterly editorial referred to:

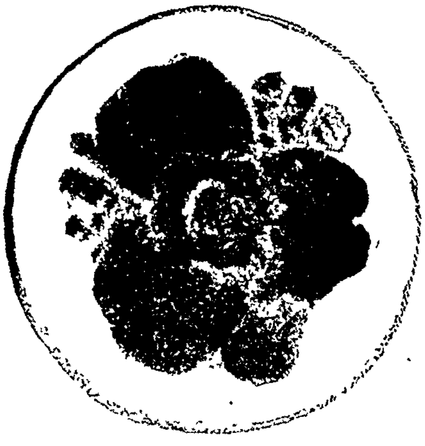
"It has been a marvel to thoughtful acousticians how the phonograph diaphragm with its central needle point was capable, under the action of the human voice, of mechanically reproducing that voice even to the most minute articulation and inflection of the spoken words. It is known to almost everybody that such a diaphragm, if spoken to with its central steel point bearing against a foil or wax cylinder revolved under it, will produce a line of hollows and ridges as the cylinder rotates while the vocal words are being directed against the diaphragm. Then if the needle be replaced in this groove of indentations at the start and the cylinder rotated as before, the friction of the needle point rubbing against the indented wax or foil, will cause the diaphragm to repeat its original vibrations so as to reproduce the very same words that were spoken against it, even to the slightest modulations of articulate speech.

"It has been roughly assumed by physicists that the whole thing was explainable by the action of air waves sent off from the vocal organs, thus causing the diaphragm to vibrate, thereby to make the vocal impressions in the wax by the point of the needle.



Seaweed or Landscape Form.

"We confess that this was our superficial view from a first examination, as we originally gave it in the 'Problem of Human Life.' But we wish it now distinctly understood that we have since revised our conclusions and repudiated air waves as having anything to do with the effects of sound known as sympathetic action upon diaphragms, tensioned strings or anything else. Indeed, we deny that a sounding instrument sends off air waves at all, even for a single inch, as a mechanical cause of the vibration of a sympathetic diaphragm such as that of the phonograph, mechanical telephones, etc.



Pansy Form.

"Sound waves, however, or sound pulses are sent off or may radiate from a sounding body, and such sound waves are pulses, not of air but of the sound force itself, which is really as substantial and objective, though immaterial as is electricity which will sliver a tree to splinters, or magnetism which will lift a piece of iron at a distance from a magnet.

"In the first place sound force is likewise assumed only to act sympathetically on a body in unison with its vibrational number; but while this is true it is also a fact that a tensioned diaphragm is really composed of many sections or subdivisions of tensional sympathy, each one of which is actuated by a tone of corresponding pitch or synchronism.

"This is proved by common experience in speaking to a tensioned diaphragm with light powder sprinkled over its surface, different varieties of pitch and peculiarities of tone distributing and arranging the powder differently according to the portions of the diaphragm most powerfully influenced by the given tone employed. And here is the sole explanation of the wonderful effects described in the beautiful achievements of Mrs. Hughes, Margaret Watts, which we have copied, by so pitching, directing and guaging the voice as to call into sympathetic action the minute tensional and unison portions of the diaphragm in such manner as to form the pictures of leaves, flowers, etc., by her peculiar distributions of the powder.

Serpent Form.

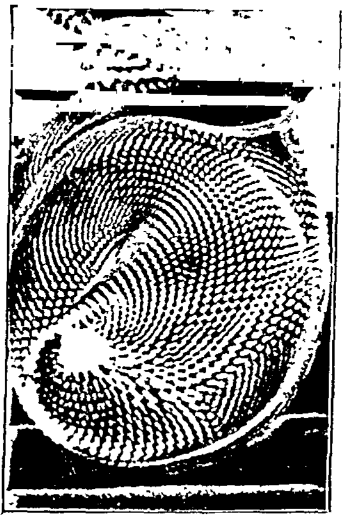
"Now it is manifest that no such sympathetic selection of tensional and unison portions of a diaphragm could be accomplished by mechanical waves of air, if such waves really exist, which dash bodily, like water waves, against the whole surface of the diaphragm whatever pitch of tone is employed, whereas, pulses of sound force can and will normally select such sections only of diaphragm as will sympathetically respond to their pitch, and thus will only move the entire diaphragm and its central needle-point incidentally by the more energetic movement of the sympathetic portion directly acted on by the sound.

"It is plain, if these analyses be correct, that such sectional vibrations of the diaphragm at all sides of the needle, according as the pitch and intensity of the tone should change, must give a slight wabbling or lateral movement to the needle point in its line of indentations as well as the appropriate varying degree of depth and distance apart of the individual impressions,

"Such a line of indentations composed of the requisite depths and alternate distances apart to correspond with the pitch and intensity of the producing sounds would also have for the needle point an almost infinitesimal lateral zigzag system of impressions, though too fine to be discovered under the microscope, by which the peculiar quality of the voice of the speaker and the articulation of words would be reproduced from the diaphragm when the needle should be caused to re-traverse the same line of indentations.

"By this forced lateral and zigzag tremor of the needle point the original sectional vibrations of the diaphragm that had actuated the needle would be reproduced, thus developing the same quality, pitch and intensity of the sound force originally liberated by a similar action of the vocal organs.

"That the needle point can and may actually produce the lateral zigzag indentations here claimed while producing the line longitudinal to the direction of the needle, and still too small to be perceived under the most powerful glass, as the real cause of the quality and articulation of speech, may rationally be inferred by the fact that the tuning-fork will liberate audible sound force when its motions are many thousand times too small to be detected under the most powerful microscope ever constructed. This was proved by our original discovery of a method for measuring the distance of a prong's travel even after sounding four minutes." (See the elaboration of that discovery by Capt. Carter, *Microcosm*, vol. iii, page 154.)



Cross-Vibration Figure.

During several years of practical application which I have given to the study of applying these two machines above alluded to, in the several sciences as well as making them to serve as an aid to medical science, I came to some positive conclusions which bore their own fruits, and which at the beginning of my studies were fully anticipated.

As a special department of medicine which involves the throat, nose, and chest diseases, I owe much to the aid already received from the phonograph and micro-phonograph. Naturally enough my practice brought me in direct contact with celebrated people and artists of high vocal culture and rank and with their already fully trained voices I began to make some investigations regarding the adoption of a standard of singing, speaking etc., for myself to judge from, with those whose training was not up to standard. Those excellent artists for instance whose records I have taken and possess, were those whose education in the art of singing accorded with various methods in vogue, such as are taught by the German, Italian and French schools, and certainly by repeating to oneself over and over again such phonograms one must become from many such comparisons a good critic in the art. It is astonishing to hear the differences in the methods that the special training of one of these schools gives to singers and also the ones to actors, elocutionists, etc., and more so again to compare those singers of a mixed school with those whose singing is simply naturally produced by their own efforts and training. What differences that wonderful tell-tale betrays! The music that is in the well trained artist rings forth its melody in its pure musical sound out of the indented pulse waves imprinted on the cylinders of the composition wax. Making these serve for comparative study with the lesser, natural and other voices, I have gained much profit in regard both to the different shades of tones and qualities possessed by their vocal organs.

It is known that with instruments made in exactly the same way, there is still perceptible, a certain difference in the shade, in the quality or the timbre of their tones. So we find it with the human voice. A certain standard is necessary in order to judge of the proper timbre-pitch and quality in a tenor, baritone and basso voice, as well as in a soprano, mezzo-*soprano*, *alto* and contralto. By bestowing some further experimental study on this subject, I am certain that shortly I will bring forward a standard as well as an additional new art to aid the learning of singing, speaking correctly the languages, elocution, acting and many other points connected with them.

Some of the records which served me for my purpose were taken from the celebrated tenors, baritones, bassos, and female voices of the New York Metropolitan Opera House, as Julius Perotti, Andreas Dippel, Carl Strietmann, Mr. Koppel, etc., Theodore Reichmann, Emile Steger, Conrad Belrens, Frl. Koschoska, Frl. Nicolini, Sig. Gorski, Mina Bertini, Helen Mora—famous contralto—Bertha Ricci, and many others less educated in singing and in the several arts. Amongst them for comparative study of elocution and acting were many celebraties from American, German, Italian and English stages.

As for the assistance derived from the phonograph and the micro-phonogrph in connection with the treatment of singers', actors', lawyers', clergymen's, etc., throats, noses and voices from a medical standpoint, they were of special use to me in phonograving their voices, when in what singers and actors call "good condition," and those were preserved for comparison in case any one of them should be taken with any ailment of the voice, thus making the normal record a standard to serve me to go by while under treatment and recovery. Also found them valuable in taking clinical phonograms for further study, as well as to demonstrate from. The following rule is one which I always adopt: To always take a record of any case that comes to me for medical relief, so that I may be able to judge of the progress of the gradual recovery of such a voice, etc., under treatment. There I have the extra aid to judge from, both the eye and the ear.

Recently I brought before the notice of the New York Medical Association by way of illustration, the project of taking and preserving records of specimen patients, which records would demonstrate a certain characteristic cough or signs,such for instance, as the whoop of whooping cough, asthmatic breathing in all its forms, stenosis of the larynx, due to whatever cause, and which is so evident in cases of cramp and diphtheria, also of the nostrils to any of their causes, the hoarseness of laryngitis, corditis, the rough breathing in tracheitis, nasal troubles, cries of babies at different periods of their growth. Stuttering, imperfect speech. To these latter two, much aid is gotten from the use of these machines as a tutor for correcting the difficulty. Sneezing, normal breathing as contrasted with the abnormal, etc. These cylinders or phonograms I have and propose to utilize as demonstrative evidence and illustration in the lecture rooms, to be added to the didactic and clinical methods of my teachings.

It is certain that students and men of our and other professions would gain more from one lecture in any branch of science, etc., thus aided by the phonograms, than from two dozen of the ordinary and prevailing ones. Cabinets may be arranged as libraries in which all kinds of records may be preserved either referring to or representing the different kinds of diseases of the throat, nose, chest, etc., and in their different stages. To such and other phonographic libraries many interesting features might be added. I am laying the first foundation to a phonogram library.

For many years I made use of the microphone, constructed on a special principle, for magnifying the sounds of the lungs, heart, throat and blood vessels, in their normal and abnormal states, and then recording them directly to the phonograph. Most interesting experiments have been its outcome. At the International Congress to be held at Rome in September, 1893, I propose to exhibit some medical micro-phonogram specimens.

Some experimental records were also made regarding the development of the natural or acoustic alphabet, but as yet I am not ready to submit a statement of any facts on account of the many difficulties still to be overcome.

Regarding the different methods of teaching which are in vogue in elocution, reading, reciting and acting, many very interesting and successful features were the outcome of these experiments and will prove valuable to those interested in those branches of study. Mr. Thomas A. Edison has interested himself in my behalf and regarding these studies, and has specially constructed for me a phonograph which has many new attachments besides some fine diaphragms on a new principle; with this aid I am now able to receive on its recorder the finest of tones and reproduce them. Hoping then to carry out further experimental researches which heretofore handicapped me by the want of proper mechanical appliances. But with such instruments as Mr. Edison has now placed in my hands, and the micro-phonograph, both which I possess as a gift from these inventors for my furthering the study already carried out, will beyond a doubt replace those appliances to any former ones in use.

With both these machines only success must follow my further research chiefly in the medical science.

Another great difficulty which has now been overcome by the Edison phonograph and Lieut. Bettini's micro-phonograph is the old one—that is, not even sacrificing the perfection of articulate speech to volume of sound. These are the latest additions made to them. The Bettini as well as the Edison machines, have become valuable instruments for teaching on account of their accurate reproduction and loudness.

Amongst some of the latest uses of the phonograph and micro-phonograph is one suggested by the daughter of Rabbi Brown, of Cleveland, that the phonograph and the micro-phonograph may be used to teach the blind to read. This Mr. Edison intends to utilize, and now is working out a method by which to reduce the size of the cylinders and yet increase their capacity. The recording needle is being reduced to half the size of the present one. The screw is made smaller so as to increase the revolutions of the cylinder. The number of words can thus be increased, with some extra alteration, to from 4,000 to 5,000 words, and the durability of these cylinders will be such as to be able to repeat the records 3,000 times. Experiments are now going on at the Edison laboratory, so that duplicates of any records may be made to any number.

Dr. H. F. Garey, of Baltimore, adapted the phonograph to the cure of deafness. He speaks of his success as being simply phenomenal, and considering the simplicity of the principle now, since it has been discovered, he is surprised that this adaptation of the phonograph for the cure of deafness was not earlier brought to light by the great aurists, whose reflected brilliancy has been shining down upon us. But it is a repetition of the same old story, proven again and again, especially in science and matters of invention, and in all great discoveries.

The principle is that the sound emanating from either the phonograph or micro-phonograph produces a massage of those parts of the ear which transmit sound to the brain, by giving continuous and successive vibrations at regular intervals. This it does with certain degrees of intensity and frequency, according to the exigencies of the case. In bad cases, a series of intensified shocks at the rate of one to the second is produced against the drum. In cases of not over five years' standing, the vibrations are given with more frequency and less intensity. This I believe is the proper caper, and records can be made to suit all kinds of cases, regarding the proper intensity of the sounds to be administered, in the same way as an electric current is given to a patient. All such records may be graded accordingly.

With some of the latest improvements of the phonograph it has been brought very near the point of perfection. It is much more simple, it is automatic in adjustment, efficient in action and easy of manipulation. An author can dictate chapter after chapter upon the cylinder by means of the phonograph, and the typewriter can put these into printed form with little trouble; thus one of these cylinders may be made to take scores of chapters and reproduce them for the press.

The phonograph has come much into use as assistant in dispatching correspondence, and it is not used in lieu of, but in connection with the stenographer. It has also come to reproduce the orations of our celebrated speakers, the recitations of skilled elocutionists and the fine effects of dramatic and vocal art.

As mentioned in my former article on this subject, as a teacher of all languages it has no equal, since it repeats with marvelous accuracy every word spoken into it with correct pronunciation, and records the finest variations and shades of sound with absolute precision.

It is a human photograph, as spoken of in *The Phonogram*, "beginning to inscribe one's words from the cradle and following one to the grave." Also has come to bring back the voice of the departed we love.

The latest use made of the phonograph is to receive messages on the telephone.

These machines have so many uses that the time is near when they will be as generally adopted as the sewing machine. What I have here spoken of is not an illusion, nor a future possibility, but that which is done each day, and as the advantages of modern electrical facilities are more appreciated, these machines will become more and more recognized factors in facilitating labor and aiding sciences in many thousand ways. I must confess that much can still be improved in them—but we are on the eve of the discovery of the final secret of the true scientific phonographs.

I would like to add in addition to these remarks that the phonograph, with its wonderful resources, is not the only instrument that Mr. Edison has added to the physician's armamentarium. In the early stages of the phonograph, great difficulty was found in procuring a battery which had the requisites for running the instrument in a safisfactory manner, and Mr. Edison, after trying every known species of battery in the market, evolved the Edison-Lalande cell, which possesses those requisites in a remarkable degree: inasmuch that it now stands before the public as the only perfect battery of the day. It was found so efficient in its work on the phonograph that it was determined to place it on the market for general purposes, and it has now been in use for upwards of three years by all the leading railroads in the country for telegraph work. Having heard that the medical profession were experiencing great difficulty in procuring satisfactory apparatus with which to administer general electrical treatment and for use in general surgical work, where the use of the electric current is necessary, Mr. Edison finally determined to adapt the battery for this kind of work, and the Edison Manufacturing Company have placed on the market a complete line of physicians' batteries, which I believe will fill a long felt want. The great requisites in a battery for medical work are the following:

1. Constancy of current, so that a physician can administer treatment with confidence that his battery is delivering a known quantity of electricity; and when it is used for running cautery knives and lamps there is no danger of the lamp or knife being burnt out, and thereby causing great annoyance to the operator. The Edison-Lalande battery has a current which is absolutely constant during the whole life of the battery.

2. No local action or waste when the battery is not in use. The local action in the Edison-Lalande battery is practically nothing, so that the battery can be left without any attention whatever, and will always be ready for work until the elements are entirely exhausted.

3. Long life. The Edison-Lalande battery in its different forms as used for galvanic and cautery work, will last the average physician a year or more, without recharging.

4. Cleanliness. The Edison-Lalande battery has no odor, nor do any salts form on the top; so that it can be placed in any convenient part of the office without destroying carpets, or causing instruments to rust from the fumes which are usually found in the batteries in use to-day.

5. Low internal resistance. The Edison-Lalande battery has practically no internal resistance, so that every particle of energy is utilized on work, instead of being partly exhausted before it leaves the battery.

The Edison Manufacturing Company have put up their batteries in handsome cases, and the equipment of each instrument is first-class in every respect. They have an exhibition here, and will be pleased to furnish any information that may be needed.

My only hope is that the next communication I make to our profession will be more fully in detail, and more profitable; thereby placing in their hands an appliance as an appreciable precision instrument to be made use of in our science.

118 E. Sixteenth St., New York City.

GYNECOLOGICAL OBSERVATIONS IN THE INSANE.

BY C. A. KIRKLEY, M.D.,
OF TOLEDO, OHIO.

The observations recorded in this paper were made at the Toledo Hospital for Insane during a part of 1890 and 1891, the opportunity being kindly given by Dr. H. A. Tobey, Supt.

Owing to the vicissitudes of politics, Dr. Tobey was succeeded by Dr. C. E. Tupper who kindly permitted the work to go on. To these gentlemen and their assistants is due the credit of facilitating in every possible way the difficult work. Acknowledgement is due Dr. Faber, one of the assistant physicians who kept a clinical record of the cases reported. Investigation in each case has been difficult, and it has been impossible to obtain reliable histories in some of them. In some cases patients had regained their normal mental condition sufficiently to give something of a correct history, but that concerning the reproductive organs in the application for admission to the hospital has been of little value. Such indefinite causes as "womb trouble," "menstrual derangement," "change of life," "child birth," etc., are usually given. While these indefinite conditions may have been factors in the production of insanity in each case, the special gynecological disease existing prior to manifestations of mental disease could only be guessed at. Whatever may be of interest in this paper therefore relates to existing disease of the reproductive organs, and the effect of its relief upon the mental condition rather than to the part those diseases play in the production of insanity. The annual report for the fiscal year ending Nov. 15, 1890, shows that of 130 first admissions, in 35, or nearly 27 per cent., the cause was attributed to some disease concerning the reproductive system, and for the year ending Nov. 15, 1891, of 130 first admissions 42, or more than 32 per cent. From these reports it is evident that a large proportion of insane women have gynecological disease, but whether these diseases produce or complicate insanity is not so clear.

June 1, 1892, there were 595 women in the hospital. Abdominal section had not been performed on a single patient so far as known, and only one case had undergone a gynecological operation. The patient was a dipsomaniac, and was suffering from complete prolapsus uteri. She was the mother of one child born five years ago, and for three years prolapsus had existed due in part to relaxation of the pelvic floor.

Since the birth of her child she became a physician and began practice, the child in the meantime dying. Domestic troubles also culminated in divorce from her husband. She was subject to attacks of violent headache at or near her menstrual time, and would resort to morphia for its relief, large quantities of that drug being necessary to control it. The severe headache was attributed in part, at least, to reflex causes. Tait's "perennial extension" operation was done resulting in complete relief of the prolapsus. Within about three weeks after the operation she was attacked with acute mania, which was more or less violent, and which lasted for about three months, and ended in apparently complete recovery. Whether the insanity was due to the combined effects of disappointment in life, grief at the loss of her child, the more or less habitual use of morphine and stimulants, and the constant irritation of the nervous system from the prolapsus, or to the operation, is impossible to determine, but it is reasonable to conclude that the operation may have produced the explosion, the other factors having played an important part.

That insanity exercises a peculiar influence upon the sexual organs of women there can be no doubt. This may also be said of insanity in men. Mrs. Etta Kelley, a faithful and competent attendant at the hospital, ascertained that of 595 inmates, perverted sexual function was known to exist in 230—nearly 39 per cent. This number admitted to her that they practiced masturbation whenever the opportunity presented itself, which, however, is not often, as the cottage plan upon which the hospital is built makes suitable classification possible, so that a patient is rarely alone. A singular fact is that most of these patients were either married or widowed, and still more surprising is the advanced age of most of them. No reliable data could be obtained as to the present social condition of many of them, but the age was ascertained in most cases:

Twenty-one were between the ages of 14 and 30; 68 between 30 and 40; 82 between 40 and 50, and 19 between 50 and 60. Only two were 14, two were 21, three were 20, and one was 22. One was 67, two were 70, and the age could not be ascertained in the remaining 29. It will be seen that the greatest number (82) practiced this unnatural habit within and during the climacteric period, and that comparatively few were among the younger women. This contradicts the frequently repeated statement that unmarried women and young girls are so given to this vice. The comparison between sane and insane in this way may not be accurate, but in defense of the former it may be said that it does not prevail to that extent that is commonly supposed, and it is extremely doubtful if any pure-minded young girl has the slightest idea of sexual desire previous to her marriage. The truth of this proposition may be questioned, and it is admitted that it is not easily proven, but it is based upon the fact that the sexual desire in women is latent as a rule, and that its actual existence, varying, of course in intensity in different women, is the result of development. Physicians are not unfrequently consulted both by young husbands and wives concerning the want of sexual desire on the part of the wife, who confesses that she has never experienced that desire as she is aware of its existence in others; that she is entirely passive, and submits to the approach of her husband only to gratify him. This uncultivated instinct in woman-kind fortifies her naturally stronger moral sense, the better qualifying her to fill her exalted position in life. A friend in discussing this subject, suggests that the young girl "does not encourage the desire, she is not tempted in any way to gratify it. It does not disturb or control her, but may she not feel it at times? The normal desire becomes abnormal under abnormal excitement and then she may reach the point of mental danger." That some girls may have experienced the desire before marriage, without having been excited may be true, but those instances are probably exceptional. The ungratified desire induces the habit of masturbation, and there is no reason to believe that the vice exists more frequently among sane than insane girls, and when it exists in the latter it is rather the result than the cause of the mental disorder.

It is a notable fact that religion as a cause of insanity goes hand in hand with sexual perversion, the reason, no doubt, existing in the emotional character of each. The foregoing statistics would suggest that whatever the cause may be that produces the mental disorder, it so disturbs, and perhaps stimulates those nerve centers that control the sexual desire, that masturbation is the result. Idleness and solitude, of course foster this vice.

The *Medical Record* of May 21, 1892, contains an interesting letter on the insane in Egypt, by Dr. H. F. Peterson, of New York, who informs us that nymphomania is very common among insane Egyptian women, and that clitoridectomy is performed on every Egyptian woman at an early age as a religious rite, which, however, does not seem to lessen the number among insane women with sexual element complications. Almost every patient has an excuse for the practice of this habit, which is only interesting as a curious delusion. One says that unless she does so she cannot urinate, another that certain women become men who outrage her, another that she was disappointed in love, etc. These patients have a strange propensity for putting foreign things into the vagina. On examination at one time a spool of thread, a stick, some paper, a piece of glass and a string were found. The patient was about 55 years old.

Many difficulties are encountered in ascertaining a correct clinical history, and the physical condition of the sexual organs in the insane. The record taken upon admission is the only reliance, as very few patients can give anything like a correct one of themselves, and one's own ingenuity must be relied upon for finding out the physical condition. Some patients actually refuse to be examined at all, others submit only under protest, and therefore constantly struggle, while in other cases in which the indications of uterine disease are quite evident an examination can only be made under anæsthesia. Reports have appeared from time to time concerning the effect of gynecological treatment upon the mental condition. Marvelous and in some instances magical effects have been reported. Within a year a case was reported in a Western medical journal, that had been insane for years. The attending physician removed the uterine appendages with a view of curing the insanity. Immediately upon recovery from the anæsthetic the mental equilibrium was restored, and had remained so ever since—a period of several months.

The results of treatment in the cases herein reported do not sustain the position that the normal mental condition is restored upon the disappearance of the gynecological disease. Seventy-five cases were treated during the period of observation, and the following are given as a type, with the result of treatment upon the mental condition in each case:

Case 1.—J. C., an Englishwoman, 44 years old, married but has never been pregnant. Has been insane four years, cause unknown. The cervix uteri was eroded and the cervical endometrium inflamed. The treatment was by curetting and the topical application of tinct. iodine and carbolic acid, as recommended by Dr. Skene, of Brooklyn. Due attention was of course given to the general health. The disease entirely disappeared and the general health greatly improved. Within a year after treatment it was ascertained that the mental condition had only slightly improved, though the patient was apparently well physically.

Case 2.—N. B. O., American, aged 25, unmarried, insane a year. The record gave heredity as the predisposing, and her mother's death as the exciting cause. The type of insanity was suicidal melancholia. She was treated for chronic endometritis, complicated by acute vaginitis probably of specific origin. The disease entirely disappeared within a few weeks, and her mental condition so much improved that she was discharged.

Case 3.—K. S., Irish, 26 years old, married, the mother of one child 18 months old. She had been insane four months, the attack coming on very soon after a miscarriage, being in very feeble health at the time and very anæmic. "General debility" was given as the predisposing cause. The form of insanity was acute melancholia. The uterus was enlarged from subinvolution, retroverted, and there was unilateral laceration of the cervix extending to the vaginal insertion. The laceration was repaired, potassium iodide given, hot water vaginal douches employed twice a day, and the displacement corrected as much as possible with a glycerine tamponade. The uterine disease was entirely relieved in due time, and her normal mental condition was completely regained. Nine months after leaving the hospital she was still in good health. The prompt recovery from insanity in this case can be directly attributed to the cure of the uterine disease.

Case 4.—A. F., American, aged 33, married, mother of three children, had been insane five years. Her record gave "child-bearing" and "anæmia" as the exciting causes, but the predisposing cause was not given. She had chronic endometritis and unilateral laceration of the cervix. The uterus was curetted and the laceration repaired. The operation accomplished all that could be desired as far as the uterine condition was concerned, and the general health somewhat improved, but a year afterward her mental condition remained unchanged.

Case 5.—M. S., German, aged 24, married, no children, had been insane a year. Syphilis was given as the cause of her insanity. She was suffering from an acute vaginitis, of probably specific origin, which had extended to the endometrium. A solution of silver nitrate, 30 grs. to the oz., was applied once a week to the inflamed surfaces, and hot water vaginal douches were employed night and morning. Constitutionally she was given ¼ gr. doses of the mercuric protoiodide. She completely recovered from the disease and her physical health very much improved. There was also slight mental improvement, which, however, was only temporary. This was probably a case of syphilitic insanity, a cerebral lesion no doubt existing. The pelvic disease, therefore, was purely incidental.

Case 6.—M. E. M., German, 45 years old, married, never pregnant, had been insane twelve years with chronic melancholia. The exciting cause given in her record was domestic trouble, and the predisposing heredity. She suffered from complete procidentia uteri. Elytrorrhaphy was done upon the anterior vaginal wall, the sutures being of silk worm gut, and the perineum was extended forward after Tait's method. There was not the slightest union in the perineal incision, or possibly it may have been separated by pressure from the impacted rectum, which the nurse had not discovered. The recto-vaginal septum, and the outer wall of the vagina, however had become a granulating surface, over which the edges of the skin were again coaptated after deundation, and secured with silver wire sutures. Perfect union and complete cure of the procidentia was the result. For two or three months the mental condition markedly improved, but a relapse occurred which left the patient but little, if any better than before the operation.

Case 7.—M. S., Irish, aged 53, married, no children, had been insane ten years. Cause of insanity unknown, type chronic melancholia. The uterus was normal and the abdomen very much enlarged from an ovarian cyst. Ovariotomy was performed from which she made a good recovery. On the afternoon of the day of the operation the nurse had occasion to go into an adjoining room. Though only absent two or three minutes, when she returned the patient was at the other end of the hall, a distance of 30 feet. Fortunately no harm resulted. Her general health greatly improved, but there was not the slightest improvement mentally.

Case 8.—M. M. B., American, aged 38, married, never pregnant, insane three years, and religious excitement given as the exciting cause. Type of insanity recurrent mania. She suffered from dysmenorrhœa, due to stenosis of the cervix uteri. This was treated by rapid dilatation, and repeated after the second menstrual epoch, she improved sufficiently to return to her home, but after two or three months she relapsed into the same insane condition, though the dysmenorrhœa was permanently relieved.

Case 9.—M. L. D., American, aged 40 years, married, mother of one child ten years old, had been insane six months with acute mania. Her record showed "uterine trouble" as the predisposing, and "menstrual irregularity" as the exciting cause. She suffered from chronic endometritis and papillary angiomata within the urethra. The uterus was curetted, and drained with iodoform gauze, the growths snipped off with scissors, and the pacquelin cautery applied. She completely regained her mental and physical health. A report from her six months afterward stated that she had not been so well during her married life. In this case the exciting cause can fairly be attributed to the urethral disease, existing in an anæmic and debilitated patient. A disease more harrassing, and capable of producing a more complete wreck of a woman's nervous system seldom occurs. Disordered menstruation is the rule among insane women. Very few menstruate regularly and naturally, and some do not menstruate at all. The general health is usually broken down, and nutrition, of course, very much impaired. A diseased nervous system coëxisting with such a condition would naturally disorder the menstrual function. Scanty menstruation is the rule, but menorrhagia sometimes occurs, when it is generally due to uterine disease.

While disease of the sexual organs exists in a large proportion of insane women, the effect upon them of the cure of those diseases hardly establishes any direct relation between the two conditions, except in occasional instances, and when that relation exists disease of the sexual system is often rather a result than a cause. The relief of any coëxisting disease in an insane woman, whatever it may be, will be of benefit to her mentally just in proportion as her general health is improved. Pathological conditions are very much the same whether they exist in the sane or insane. Functional insanity may, of course, result directly from disease of the procreative organs, but that different types of chronic insanity are very frequently the result of those diseases may be questioned. The nerves and blood vessels are intimately related to the cerebral cell, and may interrupt or even prevent its development or reparation. For its life it depends upon the parent organism, and the cause of its perpetual change must exist in some way within the nerves or capillary blood vessels or both. Stimulation beyond the possibility of repair results in injury to the cell, therefore a pathological condition must result which interferes with the functions of the brain and insanity follows. Diseases of the reproductive organs in insane women and their management presents a vast opportunity for the gynecologist, and further observation will no doubt establish the exact relation existing between those diseases and insanity. Every insane hospital should have its gynecologist, not only to provide better care for this unfortunate class of patients, but to lighten the burdens and cares of the superintendent, who in most institutions has more than his share. The future for gynecology in this field is full of promise.

PURULENT BRAIN DEPOSITS, AND PHLEBITIS AND THROMBOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

BY FRANK ALLPORT, M.D.,
OF MINNEAPOLIS, MINN.,
PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLOGY IN THE UNIVERSITY OF MINNESOTA, ETC.

(*Continued from page 528.*)

Case 47.—*Archives of Otology*, March 1882. Treated by G. S. Munson, of Albany, N. Y. Female, age 39. Left ear, chronic otorrhœa, has had partial left facial paralysis. Pain in left ear, vomiting, tinnitus aurium, no mastoid symptoms. Convulsions, right-sided headache, deafness, eustachian tubes closed, polypus in tympanum; its removal refused. November 15. Greater pain, delirium, unconsciousness, high temperature and pulse, coma. Convergent strabismus. left eye, iris unresponsive. Death.

Autopsy—Polypus of ex. meatus, semicircular canals carious. Abscess of middle lobe of cerebrum, directly above the semicircular canals, and an opening in the meninges and brain tissue connected the semicircular canals and the abscess.

Case 48.—*Lancet*, August 13, 1887. Treated by J. P. Gray. Age 26. Chronic otorrhœa, pain in and behind ear, facial paralysis, fever. Apathetic, half-comatose, paralysis and anæsthesia of left leg, delirium. Mastoid opened; no pus. Coma, hemiplegia, hemianæsthesia, death.

Autopsy—Right cerebral hemisphere covered with pus. Perforation of dura mater upon posterior surface of petrous bone, carious opening through roof of tympanum, abscess between dura mater and petrous bone.

Case 49—Transactions American Otological Society. Treated by O. D. Pomeroy. Otorrhœa; death.

Autopsy.—Abscess (diffused) of anterior and upper third of right lobe of cerebellum, carious condition of tympanum, carious opening through roof of tympanum.

Case 50.—*Archives of Otology*, June, 1889. Treated by James Finlayson and Thomas Barr. Male, age 22. Right ear, chronic otorrhœa, acute exacerbation, fever moderate, giddy, pain in jaw and behind ear, vomiting, chills, pain in frontal and occipital regions, pain in back, head retracted, right facial paralysis, constipation, stupor, vomiting, death.

Autopsy.—Congestion of pia mater, purulent exudation in frontal convolution of both sides, purulent fluid at base, in the region of the medulla. Brain adherent near right internal auditory meatus; the extreme anterior end of right cerebellum necrosed. Purulent inflammation at base of brain, granulations in tympanum and mastoid antrum, malleus and incus gone. The facial nerve was much disorganized and denuded of its bony covering by caries.

The mastoid cells, with the exception of the antrum, were obliterated and converted into a sclerosed mass. Pus in the antrum, caries of tympanum, auditory nerve disorganized, cribriform lamina destroyed by caries. On the upper part of the petrous bone a caries aperture communicated with the cochlea. Bone over the superior semicircular canals was carious.

Case 51.—British Medical Journal, Dec. 11, 1886. Treated by B. Gowers and E. Barker. Age nineteen. Right ear. Chronic otorrhœa; pain in and around ear; fever; bilateral optic neuritis; vomiting; unequal pupils; mastoid opened; improvement, but still unequal pupils, and optic neuritis persisted; again vomiting; stupor, insomnia, delirium, fever and chills.

Operation.—Skull trephined one and one-fourth inches behind and one and one-fourth inches above the centre of the meatus, or, in other words, at the lower posterior angle of the parietal bone, near the squamous suture.

Antiseptic precautions were taken. An aspirator needle was introduced into the temporal lobe, inward, forward and downward, and pus evacuated. The opening was enlarged. The brain debris was removed. A drainage tube was employed.

The after-treatment consisted of irrigations with boracic acid solution. Recovery.

Case 52.—Archives of Otology, Vol. 12, No. 1. Treated by H. Knapp. Male, age thirty-nine. Right ear. Acute purulent otitis; pain in ear and head, especially in the right occipital region; later, pain, swelling and fluctuations in left occipital region; incision at this point: pus liberated; bone denuded; wound kept open; improvement. After a time patient became worse. It was ascertained that the pus in the occipital region came from the interior of the skull. Frontal headaches; insomnia; nausea; pale; chills; fever; swelling below original opening; incised; pus found; drained; some improvement; patient became worse again; optic neuritis both eyes; another swelling appeared, upward and backward from original opening; incised; pus found; drained; probe passed into cranial cavity; pain in right side of forehead; nausea; vomiting; delirium; coma. Death.

Autopsy.—The openings in the skull referred to in the history of the case were found. At the outer surface of the lateral sinus a thick streak of pus led along the transverse sulcus to a large collection of pus at the lowest part of the sigmoid fossa. Pus in mastoid cells and tympanum. Abscess in middle and outer part of the little brain. Not encapsulated.

Case 53.—Archives of Otology, March, 1880. Treated by H. Steinbrugge. Male, age fifty-eight. Right ear. Chronic otorrhœa; vertigo; pain in right parietal region and ear; neuralgia in third branch of right trigeminus; cholesteatomatous masses in meatus and middle ear; left arm and leg partially paralyzed; impaired vision; constipation; coma. Death.

Autopsy.—Fluid blood in all sinuses. Pia-mater congested. Right temporal lobe adherent to petrous bone. Abscess in right temporal lobe. Encapsulated. Surrounding brain substance sclerosed. Left optic nerve atrophied. Perforation through right petrous bone (anterior surface) and dura-mater. Carious opening in semi-circular canals. Drum-head and ossicles gone. Tympanum badly necrosed, so that it and the mastoid antrum are thrown into one cavity, all filled with cholesteatoma.

Case 54.—Breslauer Aerztl. Zeitschr., No. 9, 1879. Treated by Otto Binswanger. Male, age fifty-one. Right ear. Neither discharge from his ears nor deafness has been observed; fever; loss of appetite; vomiting; paralysis of left arm; epilepsy; chronic convulsions; right pupil dilated.

Autopsy.—Abscess in right first frontal convolution. Encapsulated. Roof of right tympanum inflamed. Granulations in right tympanum and mastoid cells. Drum-head destroyed. Ossicles intact.

Case 55.—Archives fur Ohrenheil, 1879, No's 11 and 12. Treated by E. F. Kretschy. He publishes three cases of fatal purulent inflammation of the middle ear; histories not given.

Autopsy.—Thrombus purulent in left transverse sinus. Pus in jugular sinus, and a defect in its anterior wall, led to the necrosed petrous bone. Cholesteatoma in the tympanum. Fibrous tissue about jugular vein infiltrated with serum and pus.

Case 56.—Archives fur Ohrenheil, 1879, No's 11 and 12. Treated by E. F. Kretschy.

Autopsy.—Purulent infiltration of inner membranes of brain.

Case 57.—Archives fur Ohrenheil, 1879, No's 11 and 12. Treated by E. F. Kretschy.

Autopsy.—Abscess in left cerebellum.

Case 58.—Treated by Burckhardt. Female, age nineteen. Left ear. Chronic otorrhœa. Died of meningitic symptoms after an illness of sixteen days.

Autopsy.—Left trigeminus acousticus and facialis imbedded in pus. Purulent pia-mater. Thrombus in superior sinus. Caries of petrosal sinus canal. Polypus in tympanum. Mastoid cells absent.

Case 59.—Treated by Burckhardt. Age two and three-fourths. Death from tubercular meningitis.

Autopsy.—Partial necrosis of left wall of lateral sinus. Thrombus in lateral sinus. Carious openings of bony walls of sulcus transversus.

Case 60.—Treated by Burckhardt. Female, age seven and one-half.

Autopsy.—Ossicles gone. Caries of mastoid process. Caries of lower wall of parietal bone.

Case 61.—Treated by Burckhardt. Female, age two and three-fourths.

Autopsy.—Multiple caries on skull. Left drum-head gone. Malleus and incus gone. Necrosis of mastoid process.

Case 62.—Archives of Otology, December, 1879. Treated by Arthur Hartman. Female, age thirty-four. Left ear. Chronic otorrhœa; occasional acute exacerbations; painful mastoid; fever and chills: pain in left temple; delirium. Death.

Autopsy.—Anterior left hemisphere covered with pus, which extended to the base of the brain. Dura-mater over left tegmen-tympani was discolored and pierced by a few openings, beneath which a cavity full of pus was seen. The pus being removed, the tegmen was found to be perforated by a few small orifices which led into the tympanum. An abscess in the brain was discovered, corresponding in situation with that over the tegmen, and extending into the lateral ventricle, which, with the right and middle ventricle, was filled with pus. The spinal cord was surrounded by pus. Polypus in tympanum and some necrosis in that space. Both tegmen and antrum were perforated by small openings which led into the middle cranial fossa. Sclerosis of mastoid.

Case 63.—Archives of Otology, December, 1879.

Treated by Arthur Hartman. Male, age thirty. Left ear. Chronic otorrhœa; violent pain in left half of face, which led to facial paralysis; later, the pain involved the entire head; polypus in left middle ear; temporal bone not especially painful. Death.

Autopsy.—Purulent meningitis of posterior cerebral fossa, and an abscess in left cerebellum. The bony wall of facial canal carious. Caries of semicircular canal. Sclerosis of mastoid.

Case 64.—*Archives of Otology*, December, 1879. Treated by Arthur Hartman. Male, age thirteen. Right ear. Chronic otorrhœa; meningitis; swollen mastoid; Wilde's incision; pus liberated; delirium; coma. Death.

Autopsy.—Pus patches over brain surface. Pus at base of brain, especially at right cerebellum. Abscess in middle cranial fossa. Pus at sella turcica and left middle cranial fossa. Necrosis of tegmen-tympani. Tympanum carious. Mastoid sclerosed.

Case 65.—*Lancet*, June, 1880. Mr. Field. Male, age eighteen. Right ear. Chronic otorrhœa; pain in head. Death.

Autopsy.—Suppurative meningitis over right petrous bone. Inner mastoid surface at lateral sinus carious. Thrombus in lateral sinus. Abscess of right tempero-sphenoidal lobe and occipital lobe. Abscess in right cerebellum. Incus and stapes gone.

Case 66.—*Archives of Otology*, March, 1880. Treated by T. R. Pooley. Male, age forty-five. Left ear. Blow on left side of head, followed by deafness and otorrhœa; painful ear; tinnitus aurium; drum-head perforated; mastoid swollen, red and painful; mastoid opened; pus found; not much fever. Death.

Autopsy.—Abscess in left middle lobe. Left-sided pachymeningitis. Petrous bone carious, especially outer half of middle surface. Pus in lateral ventricle of right side of brain.

Case 67.—*American Journal of Otology*, January, 1881, page 26. Treated by C. S. Rodman, of Waterbury, Conn. Male, age twenty-one. Right ear. Chronic otorrhœa; occasional acute exacerbations; mastoid symptoms; mastoid opened; pus found. Death.

Autopsy.—Meningitis. Pus in neck between mastoid and styloid process. Mastoid carious. Caries in the inner plate of mastoid, at sulcus of lateral sinus. Caries of squamous. The lower surface of mastoid had three carious perforations in the groove next the tip of the mastoid in the digastric fossa, all communicating with the carious mastoid cells. Caries of mastoid antrum.

Case 68.—*Deutsche Medical Wochens.*, 1890, No. 48. Treated by E. Hoffman. He discovered in the course of an operation for mastoid abscess, an abscess in the occipital lobe, which he opened. Recovery.

Case 69.—*Dublin Medical Journal*, July, 1890. Treated by R. G. Patterson. Pyæmia, following a suppurating ear.

Autopsy.—Thrombus in the lateral sinus.

Case 70.—*Archives fur Ohrenheil*, March 18, 1879. Treated by Burckhardt-Merian. Female, age nineteen. Left ear. Chronic otorrhœa; meningitis. Death.

Autopsy.—Left circumscribed basilar meningitis. Fistula between mastoid antrum and superior petrosal sinus. Polypus in tympanum. No mastoid cells.

Case 71.—*Archives fur Ohrenheil*, March 18, 1879. Treated by Burckhardt-Merian. Left ear. Chronic otorrhœa.

Autopsy.—Caries of tympanum, antrum, mastoid cells and osseous wall of lateral sinus. Thrombosis of lateral sinus. Tubercular meningitis.

Case 72.—*Archives fur Ohrenheil*, March 18, 1879. Treated by Burckhardt-Merian.

Autopsy.—Caries of tympanum and antrum. Carious opening through outer wall of mastoid. Caries of parietal bone. Meningitis.

Case 73.—*Archives fur Ohrenheil*, March 18, 1879. Treated by Burckhardt-Merion. Chronic otorrhœa.

Autopsy.—Necrosis of antrum and squamous. Meningitis.

Case 74.—*Medical Times and Gazette*, May 8, 1880. Treated by Johnson. Male, age fourteen. Right ear. Chronic otorrhœa; chills; headache; thoracic pains; unsteady gait; constipation; night sweats; pupils dilated; delirium; temperature and pulse not high; coma. Death.

Autopsy.—Double pleurisy. Pus in lungs. Pus in right internal jugular vein. Abscess at apex of petrous bone. Necrosis of petrous bone near labyrinth. Blood coagulum in sigmoid sinus. Pus in tympanum.

Case 75.—*Medical Times and Gazette*, May 8, 1880. Treated by Henry Thompson. Female, age twelve. Right ear. Tuberculous; chronic otorrhœa; headache; vertigo; vomiting; dilated pupils; temperature and pulse not high; chills; involuntary defecation; cough; thoracic pains; coma; convulsions. Death.

Autopsy.—Congestion of pia-mater. Right cerebellum adherent to dura-mater. Abscess in right cerebellum. Tubercular deposits in brain. Pus in right half of posterior occipital fossa. Pus in right sigmoid sinus. Thrombus in right internal jugular vein, sub-clavian vein, vena-cava and right auricle. Lungs abscessed. Tympanic cavity, vestibule, and semi-circular canal filled with pus.

Case 76.—*Archives of Otology*, December, 1888. Treated by Henry Ferrer, of San Francisco, California. Male, age sixty. Mastoid abscess; opened mastrid. Death from hematemesis.

Autopsy.—Pus and granulations in mastoid cells and tympanum. Meningitis.

Case 77.—*Archives of Otology*, December, 1888. Treated by Lewis, of Birmingham, England. Mastoid abscess. Death.

Autopsy.—Abscess in tempero-sphenoidal lobe.

Case 78.—*Archives of Otology*, December, 1888. Treated by Lewis, of Birmingham, Ennland. Mastoid abscess. Death.

Autopsy.—Phlebitis of lateral sinus.

Case 79.—*Archives of Otology*, December, 1888. Treated by Thomas Barr, of Glasgow. Male, age twenty-one; left ear; chronic otorrhœa; headache; slow and intermittent pulse; normal or sub-normal temperature; contraction of left pupil; paresis of all ocular muscles excepting external rectus; partial right facial paralysis; paresis of right arm, with wrist-drop; mastoid opened; no pus found; skull trephined above the external meatus; brain tissue pierced with trocar; pus found; cavity irrigated; chicken-bone drainage tube; antiseptic dressing; dressing not removed for three weeks; the opening filled in with bone. Recovery.

Case 80.—*Archives of Otology*, December, 1888. Treated by Roosa, of New York City. Female, age forty-two. Left ear. Advanced Bright's disease; acute otitis; drum-head lanced; pain and tenderness at junction of temporal and occipital bones; temperature moderately high. Death.

Autopsy.—Caries of tympanum. Pus in middle ear. Seventh nerve exposed and imbedded in pus. No mastoid disease. Meningitis.

Case 81.—*British Medical Journal*, April 14, 1888. Treated by Arthur E. Braker. Male, age thirty. Right ear. Chronic otorrhœa; lateral sclerosis of spinal cord; acute exacerbation; pain in right half of head; vomiting; epilepsy; contraction of right pupil; mastoid opened; no pus; rapid emaciation; incontinence of urine; stupor; somnolence.

Diagnosis.—Abscess in tempero-sphenoidal lobe.

Operation.—Parietal bone trephined; dura-mater incised; no pus; trephined again one and one-half inches above and one and one-quarter inches behind the external meatus; a needle was passed one and one-half inches deep, forward and inward; pus found; rubber drainage tube; iodoform dressing. Recovery.

Case 82.—*New York Medical Journal*, February 25, 1887. Treated by Abbe. Acute otitis media; acute meningitis; choked disc on same side. Death.

Autopsy.—Purulent meningitis at base of cerebrum and lower surface of cerebellum. No evidence that pus had extended from the ear. The internal auditory canal showed streaks of pus, following the course of the nerve.

Case 83.—*Archives fur Ohrenheil*, vol. 26, page 84. Treated by Schmiegelow, of Copenhagen. Male. Right ear. Chronic non-suppuration; inflammation of the middle ear; suddenly seized with neuralgia of all three branches of right trigeminus, followed by right facial paralysis; right choked disc; later, purulent otitis; pain; mastoid inflammation; mastoid opened; pus and granulations found; œdema of right side of face; skull trephined at posterior cranial fossa; no pus; mastoid opening enlarged backward; improvement; later, nausea; fever; headache; vomiting; unconsciousness. Death.

Autopsy.—Diffuse purulent lepto-meningitis. Abscess in temporal lobe of cerebrum.

(*To be continued.*)

CASES ILLUSTRATING THE MODERN TREATMENT OF WOUNDS, AND THE PRINCIPLES OF ANTISEPTIC SURGERY.

Clinical Lecture delivered Oct. 1, 1892, before the Clinical Class at the Pennsylvania Hospital.

BY PROF. THOS. G. MORTON, M.D.,

ONE OF THE ATTENDING SURGEONS TO THE HOSPITAL; PROFESSOR OF ORTHOPÆDIC SURGERY IN THE PHILADELPHIA POLYCLINIC; SURGEON TO THE ORTHOPÆDIC HOSPITAL OF PHILADELPHIA.

Gentlemen:—This morning I begin my twenty-ninth annual course of clinical lectures in this hospital. I cannot do better than to devote the first part of my hour to day to the consideration of the method which I will follow in the treatment of wounds. Before showing you any cases, therefore, I propose making a few remarks upon the principles of antiseptic surgery, which we endeavor to carry out in all our operations. To some of you who have been in attendance upon these lectures in previous years, our practice here is well known; but others are here for the first time and are just commencing their studies; to these I may explain briefly the theory and practice of aseptic surgery, which will avoid the necessity of repetition and of going over the same explanation time after time after every operation during the winter, Moreover, even those to whom the antiseptic dressings are no novelty may not thoroughly appreciate the principles involved, and when they attempt to practice this system for themselves they may overlook the essential part and meet with disappointment. This is very frequently the case with physicians who think that they understand how to practice antiseptic surgery, and get unsatisfactory results, which tend to bring modern wound treatment into discredit while the fault lies entirely with themselves.

For many years, I have been using antiseptic methods in the treatment of injuries and wounds after operations, and since it was first introduced into this hospital a number of years ago, I cannot say that there has been any decided change in our methods; the results have always been so satisfactory that there has been no need of change. During this period, it is true, many minor modifications and supposed improvements in detail have been brought out by surgeons; but I cannot say that I consider them as possessing real advantage. For instance, one surgeon will bake his knives for two hours before operation; another will use only dry dressings upon wounds; still another will have some special antiseptic like biniodide of mercury or lysol; but I have not found it necessary to depart from the original methods whose value has been established by many years' experience. The antiseptic method has for its object the preservation of an aseptic condition of wounds. You may ask "Why is this necessary." Let me state at once that suppuration is a fermentation or putrefaction which goes on in wounds and which the antiseptic system is designed to prevent and protect from. Three elements are essential in order to produce this species of infection: 1. Warmth. 2. Moisture. 3. Germs.

Now, if we can exclude the germs, putrefaction will not occur, even though warmth and moisture are present; and in the same way if either of these are missing, there will be no putrefaction, even in the presence of the germs or bacteria, which, by the way, are generally present in the air, which carries them to the surface of the wounds or other places where they meet warmth and moisture, and the combination being complete, they rapidly increase. Precautions may be taken to prevent this combination so that putrefaction cannot occur, for without bacterial growth there can be no putrefaction or suppuration. Let me give you a homely illustration of this fact. Here is a case of condensed milk, which is hermetically sealed. Here is warmth and moisture; but the bacilli of the air are excluded and it is impossible to ferment as long as it is sealed up; if it were to be opened, however, and the air allowed to enter, its contents would soon be attacked by putrefactive germs, which now are excluded. Here, I give you another illustration in a piece of jerked or dried beef. The bacteria can get at it and warmth is here, but no moisture, consequently it remains sweet; if it were placed in a bucket of water, it would be attacked by bacteria in a few hours. On the other hand, when we wish to preserve food in summer time we place it on ice, or in a cold place, and the germs and moisture cannot affect it in the absence of the necessary degree of temperature. The art of preserving food by excluding germs, as in canned meats, is not altogether new since jars of preserves have been found in Pompeii, which, being hermetically sealed, had kept their contents sweet for centuries. It is evident that the ancient inhabitants of Pompeii appreciated the fact that heat and moisture would not produce fermentation, and that if the germs were excluded the preserves would keep. Then if we exclude the germs there will be no putrefaction; if we exclude moisture, there will be no putrefaction; and if we exclude warmth, there will be no putrefaction. Now, we have the germs in the air, everywhere around us. If we expose an unprotected raw surface for a very short time, germs will be deposited and in the presence of warmth and moisture, they rapidly multiply, and we will have set up the condition of suppuration, which is a form of septic infection of a wound. To prevent this infection is the problem of antiseptic surgery. In the living body, we must have warmth and moisture, we are obliged therefore to direct our efforts towards the exclusion of the germs and to the prevention of their growth by means of antiseptics.

You may ask, "What are antiseptics?" In brief, they are agents which destroy the vitality of germs. We have many remedies of this kind at our command, and new ones are constantly being introduced, but we have held fast to the one we first used, the bichloride of mercury, in solution in distilled, or recently boiled and filtered water. It is true that objections have been raised to its use because it occasionally causes irritation in a delicate skin and when freely used upon a large wound it may be absorbed and produce symptoms of mercurial poisoning; occasionally a nurse who has her hands frequently in it may be affected by it and have to lay off for a couple of weeks or so, but with ordinary care such accidents rarely happen. *Of course, in abdominal* operations, we do not use bichloride solutions; if we should sew up the abdomen and leave a couple of ounces of this solution within the peritoneal cavity, we would surely have mercurial bichloride poisoning; but for general use on the *surface of the body* and for small wounds, no such accident *need be thought* of. For the preliminary washing off of the skin a solution of $\frac{1}{1000}$ is used; for wounds a solution of $\frac{1}{2000}$ or $\frac{1}{4000}$; except in poisoned wounds, where we may apply a solution of $\frac{1}{500}$.

Here is an illustration of the *application of this* system, in the patient now before you:

"Frank B., 14 years of age, a well developed boy, who was injured by machinery on Sept. 23, and was at once brought into this hospital. *His left arm* was crushed and the tissues lacerated *nearly up to* the shoulder. On the day of admission, amputation was performed in the upper third of the arm. Previous to the operation the surface of the skin of the injured arm was scrubbed clean with *soap and* water, and afterwards washed with ether and finally with bichloride solution." The stump is a little ragged because I had to make the most of what tissue was left. The dressings applied a week ago, I will now remove. You notice there is a little *moisture due to* oozing from the wound, but not a drop of pus. The wound is perfectly sweet. My only *object in* exposing the wound now is to remove the *drainage tube* which was put in at the time of operation in order to prevent retention of the secretions in the deeper parts of the wound, and which being no longer needed can be removed and the wound *allowed* to heal up. Except along this track, the wound has united by first intention and the gut sutures have been absorbed. There are no ligatures to come away, because the gut ligatures which were used have also been absorbed. I find here a small spot of dead cellular tissue at the upper part of the wound, which was probably devitalized by the injury. The dressings will be applied as at first, and I have brought him before you in order that you may see the details of the method. The great object in view is to secure cleanliness, and all the dressings must be scrupulously clean; the antiseptic agent is only a help in this direction, the real essential condition being cleanliness, This is proved by abdominal operations where we are obliged to do without the bichloride and rely upon recently boiled, sterilized water and accomplish the object in this way. The bichloride, however, is a very efficient antiseptic; should any germs happen to get into the dressings they could not live in such an atmosphere.

Before touching the dressings or the patient I carefully scrub my hands with soap and hot water and follow this by ether and the bichloride solution ($\frac{1}{5000}$). All instruments and utensils have been sterilized by boiling water. The stump is also rendered aseptic by douching and scrubbing with bichloride solution and washing with ether. Over the line of the incision is placed some varnished silk protective in order to facilitate escape of the discharge if there should be any. This is placed directly along the wound, and then the surface is well dusted with iodoform. I do not think that iodoform is an antiseptic, but it favors healing and keeps the wound clean. Except for the expense, I would prefer aristol for this purpose, on account of its freedom from the peculiar odor which is the great objection to iodoform. Upon the well dusted surface, we place a compress of ordinary gauze wet with a solution of bichloride ($\frac{1}{2000}$), several thicknesses being used. The dressings are then confined by a roller bandage, also of gauze wet with the same solution. A layer of cotton batting, or dry absorbent cotton, is now used to envelope the stump, and a roller bandage applied to keep everything in place. These dressings need not be disturbed for a fortnight. This is precisely the same mode of dressing wounds which I used years ago, and which, I find, fully accomplishes the purpose of keeping germs out of the wound and preventing infection and suppuration. I have used it in all amputations, even of the thigh, resections, and other operations, and even these large wounds heal by first intention. It is wonderful that such serious injuries should be followed by so little disturbance of the system and so few symptoms. In this lad, for instance, the brachial plexus was exposed in the wound and the median nerve lacerated and pulled out. I can only attribute the favorable course of the case, to the prompt performance of amputation and the prevention of fermentation in the wound by the use of antiseptic dressings.

I will now show you a different kind of a case in which an operation will be done for removal of a tumor of the breast. While the patient is being etherized, I will read you her history:

"Jane T., a widow, 68 years of age, a seamstress by occupation, was admitted yesterday, Sept. 30. She states that four years ago having previously enjoyed good health, she fell and struck her right arm, causing dislocation of the shoulder. Shortly afterwards she noticed the presence of some lumps in her right breast. In June, 1889, she was admitted into the hospital and the breast was found to be cancerous and was removed by my colleague, Dr. Hunt. She made a good recovery; but about a year ago she observed a growth in the cicatrix, which slowly increased until it attained its present size, which is that of a good sized orange. It is purple in color, hard, has many vessels visible upon the surface, and has begun to ulcerate. It causes constant pain which at times is sharp and lancinating. Her general health has declined, she is quite thin and her appetite is poor. Her urine has been examined and found free from sugar or albumen." Here is a fungoid growth following an amputation of the breast and is undoubtedly malignant. When we take into consideration the age, sex, and history of the patient, and the locality of the growth, there can be no doubt as to the diagnosis being correct. The mammary gland in the female is a favorite site for carcinoma, and this is especially likely to occur where the breast has been previously affected by inflammation, or "gathered breast," during lactation, in earlier life.

In operating, the field is cleaned as in the preceding case, with soap and water, ether, and bichloride solution, the axilla having been shaved just before beginning operations. The growth is then removed by being included between two curving incisions. It is better in these cases to tear out the growth, cutting as little as possible, so as to thoroughly remove it. All hard spots in the adjacent muscles or cellular tissue are also removed, and all suspiciously hard lymphatic glands found in the neighborhood. Bleeding vessels are at once seized with the hæmostatic forceps and subsequently secured by applying catgut ligatures. I have the surface frequently irrigated by the weak bichloride solution ($\frac{1}{1000}$) during the operation. Having found that the old cicatrix is hard, I will also remove that. We have now a large gaping wound over which the skin can be brought as in a plastic operation. As the wound is superficial, a drainage tube will not be required. Catgut, interrupted, double-knotted sutures are employed, the protective is placed over the incision, iodoform dusted on freely, including the arm pit, and the gauze compress bandage, cotton and retaining roller used as on the previous case. The arm was directed to be kept to the side, to prevent traction upon the sutures, and an anodyne directed to be administered.

The modern treatment of tumors of this kind is repeated operation. There are cases, in which there has been a recurrence after extirpation twelve or thirteen times, and life has been prolonged many years. Such growths should be excised as early as possible, and the operation repeated as often as it returns. I would operate in this case, even if I knew that her liver had been invaded by secondary growths, for the reason that this tumor is beginning to ulcerate, and in the course of a few weeks, the entire surface would be converted into a foul ulcer, having such a decided odor as to make her associates very uncomfortable, so that her existence would be almost unbearable; while her strength would be undermined by the discharges, and possibly by hæmorrhages from this foul, fungous growth. This operation will cover the surface with skin and get rid of this mass of malignant growth.

While the rule is to operate, I must acknowledge that it is also the rule that the growth will sooner or later return. In my own experience of nearly thirty years in this hospital, the longest period of exemption after operation which I have seen was eleven years. In a letter which I received from Professor Agnew a short time before his death, he informed me that seven years was the longest period any of his patients had survived amputation of the breast for mammary carcinoma.

How to Sterilize Milk.—We have recently been conducting experiments upon this subject, with results so satisfactory that we are glad to be able to communicate them to our readers. The first experiments were made with a tin receptacle capable of resisting a pressure of 25 lbs. This was partly filled with water and placed in boiling water, to the action of which it was exposed for half an hour. The pressure indicator showed no very considerable increase in pressure within the closed receptacle. We then tried boiling the tin vessel in a saturated solution of salt in water, when the pressure, as indicated by the pressure gauge, rose to 4 lbs. This was the result which we expected. We accordingly proceeded to a further experiment, which consisted in boiling milk tightly sealed in strong bottles in a saturated solution of salt. Milk sterilized in this way, by boiling in the salt solution for half an hour, will keep perfectly for an indefinite length of time. We opened, a few days ago, a bottle of milk which had been thus sterilized last June (1891), and found it to be as fresh as when placed in the bottle. It is only necessary to take the precaution to allow the solution of salt in which the bottles are boiled to cool before removing the bottles. If the bottles are removed from the solution while hot, they will almost instantly burst. The vessel containing the bottles of boiling milk should be set aside and allowed to cool gradually, when the bottles should be removed and placed in an ice chest or an ordinary refrigerator. Ordinary soda-water bottles are excellent for the purpose; or beer bottles may be used. Ordinary corks may be used for the purpose, but they should be previously boiled for half an hour. They should be pressed in tightly, and fastened with wire or with a patent fastener. After the bottles have been cooled and removed from the boiling kettle, the tops should be carefully dried and, if corks are used, covered with sealing wax, such as is ordinarily used for canning purposes.

The efficiency of the salt solution is due to the fact that its boiling point is 227° F., while that of boiling milk is less than 200° F. By using different salts, a still higher temperature may be attained. For example, a saturated solution of carbonate of potash, or saleratus, boils at a temperature of 275 F., while a saturated solution of chloride of calcium boils at 355° F. These high temperatures are, however, unnecessary.—*Bacteriological World*.

On Peripheral Nephritis in Typhoid Fever.—Dr. Judson S. Bury arrives at the following conclusions from a consideration of such facts as have been recorded, and from a study of two cases which have come under his own observation: "In one set of cases we may suppose that the action on the nerves is too slight to give rise to outward manifestations, or that these are masked by the general symptoms of the fever. In another set of cases the toxic influence on the nerves appears to be revealed by a series of irritative phenomena, such as neuralgic pains, cutaneous and muscular hyperæsthesias, exaggerated reflexes, and cramps and contractures of various muscles; while, in a third group of cases, the presence of an atrophic paralysis, its distribution, progress, and associations, leave little doubt on the mind of an observer that he has to deal with a genuine parenchymatous neuritis, and frequently with one of wide distribution throughout the body."—*The Medical Chronicle*.

Glycerine in Hepatic Colic.—Dr. Ferrard concludes a communication to the French Academy as follows: 1. Glycerine administered by the stomach is absorbed in its natural state by the lymphatics, especially by the vessels which lead from the stomach to the hilum of the liver, and to the gall-bladder; it is even found in the suprahepatic veins. 2. It is a powerful cholagogue, and an excellent remedy for hepatic colic. 3. In relatively large dose (20 to 30 grammes), glycerine brings an end to the attack. 4. In small doses (5 to 15 grammes), taken each day in a little alkaline water, it prevents new attacks. 5. Glycerine, without being a lithotriptic, is nevertheless a valuable agent in biliary lithiasis.—*Journal de Médicine. de Paris*.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.
All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, NOVEMBER 5, 1892.

THE ELECTION.

Within a few days every American citizen will be called upon to exercise his privilege of franchise in voting for the chief executive and legislative officers of the Nation. After the experience of the past two years in vain efforts made to induce Congress to enact a law creating a Cabinet Officer of Public Health, with the subsequent history of conflict between National and local health authorities, the medical profession should be exceedingly careful in finding out the views of congressional candidates on these subjects, which are as vital to the welfare and prosperity of our country as that of the tariff or free trade.

In the States where governors and legislatures are to be elected, similar knowledge of the attitude of candidates should be found out and made known. Instances are not wanting where the governor of a State has to some extent brought disrepute upon our profession by the appointment of unsuitable persons as members of the State Board of Health, with the operation of which the whole medical profession is most intimately affected, and again in the appointment of a professional fledgling as Surgeon-General of the State National Guard.

Knowing as we do, that there is no interest paramount to that of the physical welfare of the people, and of physicians to that which most intimately concerns themselves and families, it behooves us to act together as one man when we go to the polls next Tuesday, and there vote only for the men who give us a reasonable assurance that they will treat our professional interests with the respect which is their due, and favor by their acts such legislation and appointments as may be shown to be necessary and in accord with the enlightenment and learning of our art and science. This is not written in the special interest of the candidates of any political party, but for the purpose of arousing physicians to a sense of their political duty to themselves. Our professional interests are as important to us as the affairs of the manufacturer and merchant to those engaged in such occupations. We can make ourselves heard at the polls. That is our ultimatum. Let us turn our faces steadily in that direction, act together according to the lines above indicated, and it won't be very long until we will be inquired of as to what we want. One effort for one day in holding tickets at the voting precincts will not be thought of as undignified or a violation of professional integrity, when we remember that such an act was done with a right motive,—a securing of the elevation and protection of the medical profession.

MEDICAL TEACHERS AND TEACHING.

The effort to raise the standard of preparation for medical study, and lengthen the course meets the hearty approval of all. But is there not needed some changes among teachers and methods of teaching? Are the medical colleges doing their work along the advanced lines of medical progress? The evils that are so apparent in the short hurried studies of young men both unprepared and unfitted for professional life are not unfrequently traceable to the teachers and their methods.

Somewhere in the past an eminent teacher was invited to read a paper before a Section of the Association at its annual meeting. He declined with thanks, giving as a reason that there was really nothing new in that field worth writing about. This is a good illustration of many surgeons, who honestly think the entire field of medicine has been explored: To them there are no frontiers of mystery, everything is clear and arranged into distinct sections, which are always the same, with but slight variations. Such teachers are literally index men, who spend their time in arranging and grouping symptoms, and who teach medicine as a great structure, with great foundations, built up in systematic layers, of etiology, symptomology, pathology and treatment. They teach that the arrangement of the facts of disease, its diagnosis, symptoms and remedies, are the only definite entities of medicine. The knowledge of which is largely one of memory, and the practice of which is that of collecting and arranging them in groups, so as to be reached practically with drugs. Until recently the examination papers of graduates brought out this observation, that proficiency was simply a matter of memory, that teachers had simply been mapping diseases and their remedies as definite facts, that never varied. The student started out with the assurance that symptoms, terminations and remedies were always the same, and as a result they failed, or became mere commercial men, who made money the main object of life.

Text-book teachers always narrow and limit the range of science: They teach as ultimate and absolute truths that which is often contradicted by experience. While it is necessary to teach a certain definite grouping of facts with a certain possible meaning, it is dangerous to give the impression that these are absolute truths. Many of the incompetents who come from colleges are crippled by this false method. They go out to practice trusting to their memory of the lectures, and supplemented by text books. They are astonished and confused at the wide variations between teachings and practice. The result is that few ever become original thinkers or investigators. The teacher is responsible. Medicine has been taught as a mass of facts simply; no inspiration, no enthusiasm to go beyond the externals, and understand the relations of the almost endless links in the drain of life; the entire time has been spent in analyzing each separate link and reducing it to a mathematical formula; everything is defined and explained, and the very spirit of medcine is crushed out. Such teachers are everywhere, in all colleges, literary and scientific. Dogmatic formulists, who always talk about "grand principles," and never go beyond definition and exact description.

Medical schools must teach something more than exact formulas and explanations. The student must be taught to study and investigate for himself, beyond all lectures and text books. He must be taught that these are only guides and aids, and that the real facts are often far beyond these levels. The prize winner and the class scholar who has answered all the questions may be a mere parrot, who after a time becomes a teacher, and narrows the range of science to his dead level of index classification. Such men are blind leaders of the blind, and the unfortunate student who passes through such hands is dwarfed and crippled as a scientific man, or loses half a life time in unlearning and correcting the errors of his medical instruction. This may seem extravagant, but a casual observation, among the incompetent men of the profession, will indicate its truth. How few men are original thinkers and students? How many men trust to the teachings of a text-book and their memory of college lectures? How many men are hunting for specifics and combinations of drugs to do this or that? How many articles in journals are devoted to explanations of symptoms and diseases? How many works arrange and group the supposed facts of medicine as if they were mathematical truths? These and many more queries suggest that raising the standard of preparation for medical study will not of itself bring into the profession better medical men.

We must have medical teachers who are scientific students and explorers, who teach the spirit of truth as well as the letter. Teachers who can inspire the student with something more than a text-book conception of the relation of facts. Then we shall have men in the profession who are always students, always investigating on the road from the lower to the higher. There are such teachers and colleges, but we sadly need more of them.

ANENT this subject, medical teachers and teachings, we observe that the question of a higher standard of medical education is proposed for the consideration of a convention of the two-term-no-requirement Southern Medical Colleges, called to meet at Louisville on the 16th of November, prox., a subject that has already been settled by the Association of American Medical Colleges.

In his public address PROF. WM. T. BRIGGS, President of the American Medical Association, demanded at Washington, D. C., in May, 1891, the exclusion from membership in that body of all the faculties of the two-term-no-requirement schools; and proposed a united stand in favor of the minimum standard of requirements of the College Association.

The convention called to meet in Louisville is expected to extricate the schools that are now operating upon the two-term plan from the dilemma into which their defiance of the resolution of the American Medical Association and the requirements of the College Association have placed them.

Instead of living up to the standard unanimously adopted by the National Convention of Medical Teachers assembled at Nashville, Tenn., May, 1890, the two-term schools hope to bridge over the present session on the promise of coming into the three-course graded system next year. They are now ready to admit they are not able to fulfill their promises to the student this year, but promise to reform next year.

Unless we greatly mistake in our reading of the signs of the times, the dawn of the day is not far hence when there will be a complete uniformity of prelimary requirements, length and number of terms of study, for the student in all American Medical Colleges, and that there will be a similar uniformity of requirement to enable a physician to practice his profession in all of the United States.

The accomplishment of these aims and ends is a fruition of the supreme purposes of the American Medical Association.

THE Preliminary Announcement of the First Pan-American Medical Congress is fresh from the office of the Secretary-General. It is imposing in size and appearance, and contains a vast amount of information pertaining to the meeting of the Congress.

The importance of this general meeting of physicians representing all countries of the Western Hemisphere cannot be overestimated. The intelligent and well directed labor of the officers of the Congress as indicated in this announcement gives an assurance of pronounced success. In order to accomplish the effective work already done by the officers of the Congress, it has been necessary to expend a very considerable sum of money for clerk hire, stationary and postage. This expense account has been met by voluntary advance registrations of those who expect to attend the sessions of the Congress. It is very much desired that every one who expects to become a member of the Congress will transmit the registration fee of $10 to Dr. A. M. Owen, Evansville, Ind.

American Public Health Association.—The twentieth annual meeting, that will convene in the City of Mexico, Old Mexico, November 29, 30, December 1 and 2 inclusive, promises to be one of the most interesting that has been held since the Nashville meeting of several years ago.

Dr. Liston H. Montgomery, of Chicago, has made arrangements with several of the railroads that lead from Chicago to Mexico—which he considers the banner route to be selected, and the topography of the country traversed and favorable auspices offered is certainly an opportunity that has seldom been afforded to any other organization.

The itinerary of route to be traversed is as follows, in special Pullman sleeping and buffet cars, without change during the entire going and returning journey: Going, leave Chicago via the Chicago and Alton R. at 11 A.M. Saturday, November 19. Arrive at St. Louis in time to leave that city at 8:10 P.M. of same day, via the St. Louis, Iron Mountain and Southern R. R., stopping over Sabbath at Hot Springs, Ark., thence Monday A.M. November 21, to Texarcana. Thence via the Texas Pacific R. R. to Longview, Tex.; thence over the International and Great Northern R. R. to San Antonio. Southern Pacific R. R. to Eagle Pass. Mexican International R. R. to Torreon, Mexico; Mexican Central R. R. to City of Mexico. From El Paso there is a choice of any one of the following three routes to return by, namely: Texas Pacific R. R. to Dallas, thence over the Missouri, Kansas and Texas R. R. to Hannial, Mo., and Chicago, Burlington and Quincy R. R. to Chicago; or Texas Pacific R. R. via New Orleans and Illinois Central R. R. to Chicago; or return as the going trip, via the Iron Mountain and Chicago and Alton railroads to Chicago.

Luxuriant appointments and perfect convenience is assured. The railroad fare is one-half rate for the lowest limited fare one way, tickets valid until December 31, or return earlier if desired. For further particulars, address Dr. Montgomery, 70 State St., Chicago, John E. Ennis, District Passenger Agent, Iron Mountain route, 199 South Clark St., Chicago, E. D. Spencer, Northern Passenger Agent Missouri, Kansas and Texas R. R., Room 12, Rookery Bld'g, Chicago.

In view of the public interest at the present time centering in epidemics, it is hoped a large number will avail themselves of this splendid and rare opportunity and exceeding low railroad fare and the commutated rate in sleeping car accommodations of attending this meeting.

DOMESTIC CORRESPONDENCE.

To the Editor of the Journal of the American Medical Association:

Dear Sir:—In your issue of The Journal of October 29, 1892, p. 510, you have published an article entitled "Observation of a Case of Purulent Otitis Media, Cerebellar Abscess, and Death in Three Weeks," as "read in the Section of Laryngology and Otology, at the Forty-third annual meeting of the American Medical Association, held at Detroit, June, 1892, by C. H. Burnett, M.D., of Philadelphia, Pa." Permit me to state that I read no paper with this title at the time and place stated above, but I did read one entitled "Observation of a Case of Acute Purulent Otitis Media, Cerebellar Abscess, and Death in Three Weeks," which has been published in full in the *International Medical Magazine*, Sept., 1892.

That which follows the incorrect title of a paper erroneously ascribed to me, in your issue of Oct. 29, 1892, is composed first, of *remarks* made by me in the discussion of Dr. Knapp's paper and others of a similar nature, and, secondly, that part in heavier type, of remarks made by me in closing the discussion on a paper I presented at the above mentioned meeting of the Section, entitled "Some Observations upon Excision of the Membrana Tympani and the two Largest Auditory Ossicles," which paper has already appeared in full in the Journal of the American Medical Association for Oct. 22, 1892.

Had I been allowed to see a proof of this article incorrectly ascribed to me, before it went to press, this mortifying error would not have occurred. Doubtless it has been due to a reportorial blunder. By publishing this note at the earliest moment you will aid materially in setting me in a true light before the readers of your valuable Journal and also greatly oblige, yours sincerely,

C. H. Burnett, M.D.

[The matter referred to by Dr. Burnett was published just as prepared for The Journal by the officers of the Section.—Ed.]

SELECTIONS.

Chemistry of Digestion.—Dr. A. L. Gillespie points out that, though hydrochloric acid is a powerful antiseptic and capable, in dilutions of 1 to 2 per cent., of inhibiting or destroying most minute organisms, the addition of proteid matter to it, and formation of what he terms proteid-hydrochlorides in the process of digestion, allows the same organisms to flourish luxuriantly, though the strength in acidity be maintained. After a meal consisting largely of proteids, generally an hour elapses before the advent of free hydrochloric acid, and the gastric juice is therefore much less antiseptic than after a meal of carbohydrate material. It is suggested accordingly that, since a typhoid or other pathogenic bacillus ingested during a heavy dinner has a more favorable opportunity for development than if it were taken with such food as porridge, it would be well, if there were any danger of poisoning by disease germs, to take nothing with a proteid meal except it had been thoroughly cooked, or, as alternatives, to live chiefly on carbohydrates, or to take some dilute hydrochloric acid after each meal.—*Medical Magazine.*

The Period of Invasion of the Prostatic Urethra in Cases of Acute Gonorrhœa.—Heisoler, in the *Perter Medicinische Chirgurgie Presse*, 1891, reports the results of his investigation of fifty cases of gonorrhœa. He finds that in twenty per cent. the prostatic urethra becomes affected in the course of the first week; in thirty-four in the course of the second week; in fourteen per cent. in the course of the third week; in twenty per cent. in the fourth week; in four per cent. in the sixth and seventh week, and in two per cent. in the second and third months. According to the author the constitutional condition does not play any rôle in the etiology of posterior urethritis.—*Univ. Med. Magazine.*

A New Local Anæsthetic.—It is reported in the Institute of Medicine in Mexico an alkaloid producing local anæsthesia has been discovered in the plant commonly known as "blood weeper."

BOOK REVIEWS.

ADDRESSES AND ESSAYS. By G. FRANK LYDSTON, M.D. Second Edition. Renz and Henry, Louisville, Ky.

In this neat and attractive little volume Dr. Lydston has gathered together some of his late contributions. We had occasion some months ago to review the first edition of these essays, and this, the second edition, comes to us increased by the addition of several late monographs.

The following are the subjects dealt with: Evolution of the local venereal disease, gonorrhœa in women, hypertrophy and hyperplasia consequent upon lesions of the genitalia, aberrant sexual differentiation, a plea for early operation in acute peritonitis, studies of criminal crania, materialism *vs.* sentiment in the study of crime, the *rationale* of extension of the spine, tropho-neurosis in the phenomena of syphilis, varicocele, observation on stricture of the urethra, the treatment of syphilis, sexual perversion, urethral and genital neuroses, a case of circinate papulo-erythematous syphilide with psoriasis palmaris syphilitica.

Where there is so much that is good it would seem invidious to single out special topics for particular mention. We cannot, however, let the occasion pass without calling special attention to the chapters on hypertrophy and hyperplasia consequent upon lesions of the genitalia, and tropho-neurosis in the phenomena of syphilis. These two monographs form an able and philosophical discussion of these subjects that will be sought elsewhere in vain. Dr. Lydston clearly differentiates the true syphilitic lesion from the more or less variable phenomena that follow syphilis, and which are similar in many respects to pathological conditions entirely disconnected with that disease. He also clearly points out that it is not the mere association of syphilis and some disease that places the former in an etiological relation with the latter, but that the syphilization acts as a predisposing factor, by lessening the resistance of tissues. In this is furnished an explanation of the uselessness of antisyphilitic treatment in so many cases in which syphilis is thought to be an etiological factor. In these cases the lesion has ceased to be syphilitic, and remedies that ordinarily control those conditions are no longer effectual.

The articles on the study of crime, sexual perversion and criminal crania, show a wide grasp of these difficult subjects. The classification of sexual perversion proposed by Dr. Lydston has been extensively adopted by American alienists.

The volume as a whole displays marked originality of thought, clearly and logically expressed. We can recommend the "Essays" not only to the studious and thoughtful physician, but also to the active practitioner engaged in his daily battle with disease.

MISCELLANY.

THE CHICAGO GYNECOLOGICAL SOCIETY held its fourteenth annual meeting at the Grand Pacific Hotel, Friday evening, October 28, 1892. After the banquet the topic for discussion was: "How Best May we Further the Interests, Scientific and Social, of the Society, During the World's Fair Year?" Officers for the ensuing year were elected as follows: President, Dr. E. J. Doering; First Vice-President, Dr. F. Henrotin; Second Vice-President, Dr. Franklin H. Martin; Secretary, Dr. Henry Parker Newman; Treasurer. Dr. A. H. Foster; Editor, Dr. W. S. Christopher.

ON the 27th of October the Hospital College of Medicine, Medical Department of the Central University of Kentucky, abolished the clinical lectureship on the eye, ear and throat, heretofore occupied by S. G. Dabney, M.D., Professor of Physiology.

MEETING OF THE INTERNATIONAL MEDICAL CONGRESS (AMERICAN PUBLIC HEALTH ASSOCIATION) in the city of Mexico, Nov. 29th., 30th., and Dec. 1st. and 2nd., 1892., the elegant special Pullman Car to convey the delegates and their families from Chicago to the city of Mexico and return, will leave Chicago Nov. 19th., 11 A.M. The car is rapidly filling up. Among the number who have engaged space are: Dr. C. M. Hewett, wife and daughter, Red Wing, Minn.; Prof. DeLaskie Miller, Chicago; Prof. R. C. Kedzie, Michigan; W. A. Morrison, St. Louis; Dr. E. S. Cook, Mendota, Ill.; Dr. C. C. Hunt, Dixon, Ill.; Mrs. L. Miller, Cincinnati: Receptions will be given the party at Hot Springs, Ark. San Antonio, Tex. and other points. Meals will be served on the special car at net cost. No such arrangements for a luxurious trip at so slight an expense have ever been offered. Applications for space in this car should be made at the earliest moment possible. For further information, maps, time-tables, etc., address, John E. Ennis, D. P. A., Mo. Pac. Ry., No. 199 Clark St., Chicago, Ill.

WANTED.—Will pay 10 cents per copy for the following numbers of THE JOURNAL: Vol. 2, No. 4, Jan. 26; No. 19, May 2, 1884. Vol. 5, No. 2, July 11; No. 3, July 18, 1885. Vol. 6, No. 6, Feb. 6, 1886. Vol. 15, No. 1, July 5; No. 4, July 26; No. 5, Aug. 2; No. 11, Sept. 13; No. 13, Sept. 27, 1890. Vol. 16, No. 1, Jan. 10; No. 2, Jan. 17; No. 3, Jan. 24, 1891. Vol. 17, No. 3, July 18, 1891.

OFFICIAL LIST OF CHANGES in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from October 22, 1892, to October 28, 1892.

Capt. Freeman V. Walker, Asst. Surgeon U. S. A., granted leave of absence for one month, to take effect on arrival of First Lieut. George D. De Shon, Asst. Surgeon U. S. A., at Ft. D. A. Russell, Wyo.

First Lieut. George D. De Shon, Asst. Surgeon U. S. A., is relieved from duty at Columbus Bks., Ohio, and will report in person to the commanding officer, Ft. D. A. Russell, Wyo.

Capt. Eugene L. Swift, Asst. Surgeon, so much of S. O. 230 as relates to change of station, is suspended until further orders, and he is granted leave of absence for one month, on account of sickness, with permission to apply for an extension of one month.

Major John C. J. Happersett, Surgeon U. S. A., is relieved from duty at Ft. Custer, Mont., and will report in person to the commanding officer, Ft. Keogh, Mont., for duty at that post, relieving Major Philip F. Harvey, Surgeon. Major Harvey, on being relieved from duty by Major Happersett, will repair to West Point, N. Y., and report in person to the Superintendent of the U. S. Military Academy, for duty at that post, relieving Major Henry McElderry, Surgeon. Major McElderry, on being relieved by Major Harvey, will repair to Omaha, Neb., and report in person to the commanding General, Dept. Platte, for duty as attending surgeon and examiner of recruits at Omaha.

First Lieut. Allen M. Smith, Asst. Surgeon U. S. A., is relieved from further duty at Ft. Assiniboine, Mont, and assigned to duty at Ft. Custer, Mont., where he has already been ordered to temporary duty.

Capt. Edward R. Morris, Asst. Surgeon U. S. A., is relieved from duty at Ft. Custer, Mont., and will report in person for duty to the commanding officer, Ft. Warren, Mass., relieving Capt. Peter R. Egan, Asst. Surgeon U. S. A. Capt. Egan, on being relieved by Capt. Morris, will report in person to the commanding officer, Ft. Custer, Mont., for duty at that post.

First Lieut. William E. Purviance, Asst. Surgeon U. S. A., is relieved from duty at Jefferson Bks., Mo., and will report in person to the commanding officer, Ft. Sherman, Idaho, for duty at that post, relieving Capt. William W. Gray, Asst. Surgeon. Capt. Gray, on being relieved by Lieut. Purviance, will report in person to the commanding officer, Ft. Schuyler, N. Y., for duty at that post.

Vol. XIX. CHICAGO, NOVEMBER 12, 1892. No. 20.

ORIGINAL ARTICLES.

CATARRAL SORE THROAT IN THE LAKE REGION.

Read before the Section of Laryngology and Otology, at the forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY J. M. G. CARTER, M.A., M.D., Sc.D, Ph.D.,
WAUKEGAN, ILL.
PROF. OF PATHOLOGY IN THE COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO, FELLOW OF THE AMERICAN ACADEMY OF MEDICINE, ETC., ETC.

I wish to premise that the discussion of our subject in this paper is from the point of view of a general practitioner, not that of a specialist.

I shall use the term catarrhal sore throat, in this connection, to indicate that class of diseases, whether of the tonsils, pharynx or the larynx, where there is actually present or where there exists a strong tendency to a catarrhal inflammation of all these organs. In order to limit my meaning more definitely, I will refer briefly to the fact that all inflammations of the throat, of whatever form, may be classified as catarrhal, croupous and diphtheritic. A catarrhal inflammation, whether mucous, serous or purulent, is accompanied by an exudate which has no tendency to coagulate. A croupous inflammation is accompanied by an exudate which contains a greater amount of albumin and fibrin than the catarrhal variety, and consequently does tend to coagulate and form what is termed a false membrane. A diphtheritic inflammation causes the epithelial cells (which only suffer desquamation in the other two forms) to die on the spot, the exudate coagulates, and the deeper tissues are involved in the destructive process. It is evident that the croupous and diphtheritic forms may be introduced by the catarrhal form. The variety of which I speak now, however, is a catarrhal inflammation which usually terminates in three to five days, without croupous or diphtheritic inflammation supervening to any marked degree.

In the last nine years, during which I have resided on the shore of Lake Michigan, I have observed several thousand cases of throat disease in various forms. The form which has constituted by far the greater number of cases has been catarrhal, reaching in number more than two thousand, sometimes tonsillitis, sometimes laryngitis, and sometimes pharyngitis, but in the majority of instances the entire throat was involved.

I have noticed, particularly in relation to the catarrhal forms, that changes in the weather were followed by an increased or decreased number of cases, according to the elemental conditions of the change. Among these were variations of ozone, temperature, humidity, and direction and force of the wind. We are told by Sir E. Solly[1] that the proper proportion of ozone in the atmosphere is about 1 to 700,000. This would not disturb the most sensitive mucous membrane, but when this ratio is perceptibly increased, ozone acts as an irritant. M. Girerd[2] of Panama informs us that ozone transforms albumin into fibrin, and hæmoglobin into oxyhæmoglobin. The continued and prolonged action of ozone on the fibrin thus produced, reduces it to a natural state, and renders it incoagulable.

If other conditions are likewise unfavorable, catarrhal diseases of the throat and respiratory tract occur more frequently in damp weather, particularly if accompanied with cold. In such weather there is an increase of CO_2, and an excess of electricity. A venous distension occurs in damp weather (Weber), which produces a passive hyperæmia of the mucous membrane, and disposes to catarrh. Dr. Weber further states that dry air also irritates mucous membranes, disposing to catarrhal affections. The dry air takes moisture from the mucous membrane of the respiratory passages by evaporation. The body loses moisture in such an atmosphere, the circulation is increased, the mucous membranes become hyperæmic and more easily excited by irritants. And it is under conditions of dry air and the like after storms that ozone occurs in excess, and acts as an irritant.

It is known to scientists, as related by Reclus,[3] that the air of America is moister than that of the Old World in general, and this increased moisture results from the fact that the American Continent is narrower and more largely influenced by sea breezes. This will help to explain the frequent occurrence of catarrhal epidemics of various kinds in our country—catarrhal diseases of the respiratory tract in the northern portions, and of the alimentary tract in southern regions. From this it appears that cold air with moisture tends to produce catarrhal diseases of the respiratory tract, while warm air with moisture disposes to catarrh of the alimentary tract. The most agreeable humidity for breathing is 70 to 80 per cent., the diminished evaporation from the lungs causing the air to be less irritating to the respiratory mucous membrane.

We are informed by Parkes[4] that there is a tendency to catarrh over soils which contain ground-water, and where springs are abundant. Wagner[5] states that strong winds, especially from the east and north-east, cause catarrh to grow worse, and of course must act as a cause of acute attacks.

Dr. N. S. Davis,[6] of Chicago, gives the opinion, as a result of his experience and observation, that high winds, either northeast, northwest, or west, are to be considered factors in the production of catarrhal affections of the respiratory tract, but that these winds bear some relation to mountain elevation or ocean currents. He further gives some interesting and valuable statistics from a laborious work of Daniel Drake[28] compiled from army records. It is stated there that the number of cases of catarrhal diseases of the respiratory passages occurring at Fort Snelling, near St. Paul, Minn., was 600 in 1000 soldiers, and at Fort Dearborn, Chicago, was 102 in 1000 soldiers. Other posts are included in his report, and from these Dr. Davis is led to the conclusion that the important factors in the production of this class of diseases are cold, variableness, moisture and high winds. After reviewing a large area and many causes, Dr. Drake gives the ratio of cases occurring at different times in the year as 119.8 in the first quarter, 72.7 in the second, 48.7 in the third, and 99.6 in the fourth. He further makes the statement that the number of cases decreases in the ratio of 31.5 for each degree of latitude, going south.

In a paper [7] read before the Chicago Medical Society, Nov. 16, 1885, I stated that in the epidemics of tonsillitis which had occurred in Waukegan, Ill., I had observed an excess of ozone in the atmosphere, and east or northeast winds preceding and accompanying the outbreaks. The Michigan State Board of Health and others (Earle [8]), have since made similar observations.

It would be a matter of great interest to know the influence of this climate upon the aborigines, in the causation of catarrhal troubles, but so far as I am aware, *the investigations in this direction* are not sufficiently extensive to enable us to form a very satisfactory opinion in the matter.

We are informed by Cohen[9] that the North American Indians are subject to such catarrhal affections as afflict the white population, and that they ward off catarrh and acute sore throats by sleeping enveloped in blankets, and breathing through the partially closed fist. Another authority [10] states that bowel troubles are the most frequent form of disease among the Indians. The probability is that the same etiological factors are at work among aboriginal races as are found to produce pathological conditions among acclimated peoples; namely, that cold and damp climates tend to produce catarrhal affections of the respiratory passages, while warm and moist climates dispose to like disease of the alimentary canal.

During the year ending March 31, 1892, I treated 389 cases of catarrhal sore throat, not including the patients treated in my office practice. These cases occurred as follows: April, 38 cases; May, 23; June, 10; July, 13; August, 20; September, 15; October, 20; November, 26, December, 44. January, 73; February, 66, March, 41. The ratio here, when compared with that mentioned in Dr. Drake's report, given above, will indicate that the same etiological factors have operated in the causation of these catarrhal affections, the difference being due to the fact that his report refers to an extensive area of territory, while mine is confined to an area of not exceeding 120 square miles. He gives the ratios, first quarter, 119.8; second quarter, 72.7; third quarter, 48.7; fourth quarter, 99.6. In my cases the ratio was: first quarter, 120; second, 47.3; third, 32; fourth, 60. During the winter half of the year, that is, from November 1 to May 1, I had 288 cases, while in the warm or summer half, that is, from May 1 to November 1, I had 101 cases. I think that the excess of my ratio above his in the first quarter, *i. e.*, January, February and March, is due largely to the presence of the lake, and perhaps also to the ground water under Waukegan, indicated by the numerous springs found there. The average temperature in January, from 1871 to 1880, at St. Paul, Minn., was 15° F.; that at Waukegan, Ill., was 25°, a difference of 10°. This may be considered an average climatic difference. Now an atmosphere at 25°, other things being equal, will contain more moisture than one at 15°, and a cold moist air has a greater tendency to produce catarrhal affections of the respiratory organs than a cold dry air. The average per cent. of humidity at these two places is about the same. The presence of the lake keeps the air at Waukegan, especially when the wind is N.E., E. or S.E., heavily loaded with moisture, so that the humidity is higher, and as the wind during the three months named is cold, the excess of cases of catarrhal throat disease in Waukegan, above the ratio given in the large area included in Dr. Drake's investigations, is readily understood. This excess does not occur when compared with St. Paul alone. Hence I reiterate my opinion that the relations of temperature, humidity, winds, ozone, and very likely electricity, are very important, if not the chief, factors in the production of catarrhal diseases of the respiratory passages.

Another fact which I have observed in these cases, as well as in cases apparently due to la grippe, is that they are more frequent after cyclonic disturbances. This has also been observed by others. The same statement may be made with regard to true croup and diphtheria.

The course which some of these cases take, their infectious nature and the swelling of the cervical glands, and the submucous infiltrations (Baginsky[14]) that also frequently occur, lead us to believe that many of them are of bacterial origin. In all probability it will be found in these cases, as Dr. Pfeiffer[11] and others have found in the influenza of la grippe, that there is a bacillus in the blood and sputum. It is very likely that the climatic elements enumerated above so impress the respiratory mucous membrane *as to furnish a suitable soil for the cultivation* and growth of the particular form of bacillus or coccus *which causes the disease. As it is known that the* mouth is a focus for bacteria and micrococci (W. B. Miller[13]), it may be the more easily believed that some of these sustain an etiological relation to catarrhal sore throats. Indeed, various authors (Dubousquet–Labordere[15]) of late have maintained the contagiousness of tonsillitis, as well as other catarrhal diseases. Gulland[16] affirms that a function of the tonsils is the reproduction of leucocytes. In catarrhal disease this function is interfered with, and hypertrophy results, but in debilitated patients the arrest of this function may cause bacteria to enter the tonsils. I believe, however, with Allen,[20] that the natural condition of enlargement of the tonsils which occurs in children and youth is often mistaken for hypertrophy from disease.

It is interesting to note, in this connection, that horses are affected, in epidemics of catarrhal diseases of the respiratory passages, a few weeks before members of the human family are attacked (Fleming[20]).

It is a matter of common observation that some persons are more susceptible to catarrhal diseases than others; that is, the power of resistance to disease, which every one has to a certain extent, is so strong in some individuals that they will pass through an epidemic unharmed, while the more susceptible are first affected. Those who are susceptible to catarrhal sore throats are liable to have recurrent laryngitis, pharyngitis and tonsillitis, until a chronic form may result. The increased number of capillaries in the cuboid space posterior to the nares (Flint[17]) renders that region a favorite retreat for chronic catarrh.

The habit of wearing mufflers about the neck is liable to make the throat more sensitive, by being usually kept in a state of perspiration, which permits a refrigeration of the skin to occur more easily, and the reflux of blood to the dense network of capillaries in the larynx (Landois[18]) and adjacent mucous membrane produces congestion, and consequent catarrhal sore throat.

The attack usually begins suddenly. It is characterized by general muscular soreness or aching, chilliness, sometimes pain in the back and back of the neck, generally a sense of stiffness in the throat and neck, nausea, temperature increased, varying from 102° to 105°. Generally the entire throat is in a state of catarrhal inflammation, the most susceptible part (*pars minoris resistentiæ*), suffering the most intensely. The tonsils are sometimes covered with small patches of coagulated material, while the remainder of the throat is involved only in catarrhal inflammation. The active symptoms subside in three to five days, and complete recovery occurs within a week. When the glands are much enlarged, as occasionally happens, it may be two weeks before they return to the normal size. The glands are often slightly enlarged, but subside with the fever. They all terminate in recovery. However, it occasionally happens that cases of diphtheria occur during these endemics. It is generally easy to distinguish the one from the other by the second day of the disease, and often from the beginning. Another important fact is that it not unfrequently occurs in a family where there are several cases of the disease, that one will take the form of diphtheria. Albumin has been found in the urine of many of these cases (Ingals[20]), but it is probably due to the same causes which explain its presence in other febrile diseases.

Hot wine gargles have been recommended in these sore throats. Lennox Browne states that menthol, an antiseptic and local anodyne, contracts the capillaries of the nose and throat, and checks secretion, and in consequence of these virtues recommends it in hoarseness and soreness of the throat, in this class of troubles (Bishop[20]). My own experience with this remedy is that in certain cases it acts well, but in other cases it fails to give relief. I have thought that in cases occurring in damp weather, when the mucous membranes are in a state of venous distension, the inhalation of menthol produced better results than in dry weather. The same is largely true of astringent gargles. In dry cold weather, when the mucous membrane is constantly parting with the moisture which forms nature's covering, some more bland treatment will succeed better. In these cases the spray of vaseline (Robinson[21]), or vaseline applied with a soft brush or absorbent cotton, acts very soothingly. I have also in such cases used a gargle consisting of alcohol, glycerine and water, varying the proportions to suit the sense of dryness in the throat.

I have found gargles of milk to be very excellent in the dry form, hot, warm or cold, as the patient prefers. I have been especially pleased with the results of ice and cream. The ice is to be shaved or scraped, and mixed with sweet cream, in the proportion of one of ice to two of cream. This is particularly valuable in small children, who cannot or will not gargle, nor allow the spray to be used. Sugar may be added, or any flavoring extract, to suit the taste. In older patients, the ice and cream may be used in equal proportions. Ice cream serves an excellent purpose in many cases, to control the nausea. This treatment acts well also in those medium cases, where it is difficult to decide whether they should be classed with the dry or moist form.

The essential oils, by spray or nebulization, are also valuable in these dry forms, and are usually very agreeable.

The treatment by anatomization, since its recommendation by Jean Sales-Girons,[22] and later by Dr. Pserhofer[23] before the French Academy, has become very popular, as it deserves to be.

Solutions of chlorate of potash and permanganate of potash, and other astringent preparations, are useful when sprayed into the throat, in the forms of sore throat where the secretion is profuse. They may also be used in the form of gargles. Dr. Gabrilovicz[24] recommends inhalations of peroxide of hydrogen. I have used the peroxide, but it seems to me to be adapted to a special class of cases, or at least to serve a better purpose in special cases, where there is a tendency to the formation of a pelicle on the tonsils, or where the whole secretion is too albuminous. I like to use it as a spray in such cases, and believe its action to be similar to that of the continued action of ozone; that is, I believe it acts beneficially by dissolving the albuminous pelicle when it has been formed, and when it has not already appeared by rendering the exudate incoagulable. If this view is correct, it will be found valuable in the form of inhalation and spray in diphtheria, true croup, and those cases of tonsillitis and sore throat where the exudate contains an excess of albumin and fibrin. Yerba Reuma[25] by atomization is sometimes very valuable. Cases of croupal laryngitis (Curtin and Watson[26]), are best treated by inhalations, although atomization acts well, and the remedy should be determined, as in cases of general sore throat, by the class of inflammation, whether dry or moist. The patient should be kept in bed. Coupard and Saint Hilaire recommend a 3 per cent. solution of antipyrine in catarrhal laryngitis.

In nearly all cases where there is general febrile disturbance, I have found the use of aconite and belladonna (Ringer[27]) invaluable. An excellent protection for sensitive throats is the use of a silk handkerchief in front of the neck, in place of mufflers around it.

When all has been said, it remains to the physician to determine what the treatment in any particular case shall be, not by what the books say, but by studying the class of inflammation present, and the condition and idiosyncrasies of his patient. Then by the use of medicated inhalations and medicated sprays, the cold compress to the throat in croupal cases, together with simple gargles and some simple preparation to equalize the circulation and reduce the temperature, all these cases will recover. The minimum amount of medication that will suffice and the maximum amount of care that can be secured in nursing should be the rule here, as in the treatment of all diseases.

ing, near St. Paul, Minn., was 600 in 1000 soldiers, and at Fort Dearborn, Chicago, was 102 in 1000 soldiers. Other posts are included in his report, and from these Dr. Davis is led to the conclusion that the important factors in the production of this class of diseases are cold, variableness, moisture and high winds. After reviewing a large area and many causes, Dr. Drake gives the ratio of cases occurring at different times in the year as 119.8 in the first quarter, 72.7 in the second, 48.7 in the third, and 99.6 in the fourth. He further makes the statement that the number of cases decreases in the ratio of 31.5 for each degree of latitude, going south.

In a paper [7] read before the Chicago Medical Society, Nov. 16, 1885, I stated that in the epidemics of tonsillitis which had occurred in Waukegan, Ill., I had observed an excess of ozone in the atmosphere, and east or northeast winds preceding and accompanying the outbreaks. The Michigan State Board of Health and others (Earle [8]), have since made similar observations.

It would be a matter of great interest to know the influence of this climate upon the aborigines, in the causation of catarrhal troubles, but so far as I am aware, the investigations in this direction are not sufficiently extensive to enable us to form a very satisfactory opinion in the matter.

We are informed by Cohen[9] that the North American Indians are subject to such catarrhal affections as afflict the white population, and that they ward off catarrh and acute sore throats by sleeping enveloped in blankets, and breathing through the partially closed fist. Another authority [10] states that bowel troubles are the most frequent form of disease among the Indians. The probability is that the same etiological factors are at work among aboriginal races as are found to produce pathological conditions among acclimated peoples; namely, that cold and damp climates tend to produce catarrhal affections of the respiratory passages, while warm and moist climates dispose to like disease of the alimentary canal.

During the year ending March 31, 1892, I treated 389 cases of catarrhal sore throat, not including the patients treated in my office practice. These cases occurred as follows: April, 38 cases; May, 23; June, 10; July, 13; August, 20; September, 15; October, 20; November, 26, December, 44. January, 73; February, 66, March, 41. The ratio here, when compared with that mentioned in Dr. Drake's report, given above, will indicate that the same etiological factors have operated in the causation of these catarrhal affections, the difference being due to the fact that his report refers to an extensive area of territory, while mine is confined to an area of not exceeding 120 square miles. He gives the ratios, first quarter, 119.8; second quarter, 72.7; third quarter, 48.7; fourth quarter, 99.6. In my cases the ratio was: first quarter, 120; second, 47.3; third, 32; fourth, 60. During the winter half of the year, that is, from November 1 to May 1, I had 288 cases, while in the warm or summer half, that is, from May 1 to November 1, I had 101 cases. I think that the excess of my ratio above his in the first quarter, *i. e.*, January, February and March, is due largely to the presence of the lake, and perhaps also to the ground water under Waukegan, indicated by the numerous springs found there. The average temperature in January, from 1871 to 1880, at St. Paul, Minn., was 15° F.; that at Waukegan, Ill., was 25°, a difference of 10°. This may be considered an average climatic difference. Now an atmosphere at 25°, other things being equal, will contain more moisture than one at 15°, and a cold moist air has a greater tendency to produce catarrhal affections of the respiratory organs than a cold dry air. The average per cent. of humidity at these two places is about the same. The presence of the lake keeps the air at Waukegan, especially when the wind is N.E., E. or S.E., heavily loaded with moisture, so that the humidity is higher, and as the wind during the three months named is cold, the excess of cases of catarrhal throat disease in Waukegan, above the ratio given in the large area included in Dr. Drake's investigations, is readily understood. This excess does not occur when compared with St. Paul alone. Hence I reiterate my opinion that the relations of temperature, humidity, winds, ozone, and very likely electricity, are very important, if not the chief, factors in the production of catarrhal diseases of the respiratory passages.

Another fact which I have observed in these cases, as well as in cases apparently due to la grippe, is that they are more frequent after cyclonic disturbances. This has also been observed by others. The same statement may be made with regard to true croup and diphtheria.

The course which some of these cases take, their infectious nature and the swelling of the cervical glands, and the submucous infiltrations (Baginsky[11]) that also frequently occur, lead us to believe that many of them are of bacterial origin. In all probability it will be found in these cases, as Dr. Pfeiffer[11] and others have found in the influenza of la grippe, that there is a bacillus in the blood and sputum. It is very likely that the climatic elements enumerated above so impress the respiratory mucous membrane as to furnish a suitable soil for the cultivation and growth of the particular form of bacillus or coccus which causes the disease. As it is known that the mouth is a focus for bacteria and micrococci (W. B. Miller[13]), it may be the more easily believed that some of these sustain an etiological relation to catarrhal sore throats. Indeed, various authors (Dubousquet–Labordere[15]) of late have maintained the contagiousness of tonsillitis, as well as other catarrhal diseases. Gulland[16] affirms that a function of the tonsils is the reproduction of leucocytes. In catarrhal disease this function is interfered with, and hypertrophy results, but in debilitated patients the arrest of this function may cause bacteria to enter the tonsils. I believe, however, with Allen,[20] that the natural condition of enlargement of the tonsils which occurs in children and youth is often mistaken for hypertrophy from disease.

It is interesting to note, in this connection, that horses are affected, in epidemics of catarrhal diseases of the respiratory passages, a few weeks before members of the human family are attacked (Fleming[20]).

It is a matter of common observation that some persons are more susceptible to catarrhal diseases than others; that is, the power of resistance to disease, which every one has to a certain extent, is so strong in some individuals that they will pass through an epidemic unharmed, while the more susceptible are first affected. Those who are susceptible to catarrhal sore throats are liable to have recurrent laryngitis, pharyngitis and tonsillitis, until a chronic form may result. The increased number of capillaries in the cuboid space posterior to the nares (Flint[17]) renders that region a favorite retreat for chronic catarrh.

The habit of wearing mufflers about the neck is liable to make the throat more sensitive, by being usually kept in a state of perspiration, which permits a refrigeration of the skin to occur more easily, and the reflux of blood to the dense network of capillaries in the larynx (Landois[18]) and adjacent mucous membrane produces congestion, and consequent catarrhal sore throat.

The attack usually begins suddenly. It is characterized by general muscular soreness or aching, chilliness, sometimes pain in the back and back of the neck, generally a sense of stiffness in the throat and neck, nausea, temperature increased, varying from 102° to 105°. Generally the entire throat is in a state of catarrhal inflammation, the most susceptible part (*pars minoris resistentiæ*), suffering the most intensely. The tonsils are sometimes covered with small patches of coagulated material, while the remainder of the throat is involved only in catarrhal inflammation. The active symptoms subside in three to five days, and complete recovery occurs within a week. When the glands are much enlarged, as occasionally happens, it may be two weeks before they return to the normal size. The glands are often slightly enlarged, but subside with the fever. They all terminate in recovery. However, it occasionally happens that cases of diphtheria occur during these endemics. It is generally easy to distinguish the one from the other by the second day of the disease, and often from the beginning. Another important fact is that it not unfrequently occurs in a family where there are several cases of the disease, that one will take the form of diphtheria. Albumin has been found in the urine of many of these cases (Ingals[20]), but it is probably due to the same causes which explain its presence in other febrile diseases.

Hot wine gargles have been recommended in these sore throats. Lennox Browne states that menthol, an antiseptic and local anodyne, contracts the capillaries of the nose and throat, and checks secretion, and in consequence of these virtues recommends it in hoarseness and soreness of the throat, in this class of troubles (Bishop[20]). My own experience with this remedy is that in certain cases it acts well, but in other cases it fails to give relief. I have thought that in cases occurring in damp weather, when the mucous membranes are in a state of venous distension, the inhalation of menthol produced better results than in dry weather. The same is largely true of astringent gargles. In dry cold weather, when the mucous membrane is constantly parting with the moisture which forms nature's covering, some more bland treatment will succeed better. In these cases the spray of vaseline (Robinson[21]), or vaseline applied with a soft brush or absorbent cotton, acts very soothingly. I have also in such cases used a gargle consisting of alcohol, glycerine and water, varying the proportions to suit the sense of dryness in the throat.

I have found gargles of milk to be very excellent in the dry form, hot, warm or cold, as the patient prefers. I have been especially pleased with the results of ice and cream. The ice is to be shaved or scraped, and mixed with sweet cream, in the proportion of one of ice to two of cream. This is particularly valuable in small children, who cannot or will not gargle, nor allow the spray to be used. Sugar may be added, or any flavoring extract, to suit the taste. In older patients, the ice and cream may be used in equal proportions. Ice cream serves an excellent purpose in many cases, to control the nausea. This treatment acts well also in those medium cases, where it is difficult to decide whether they should be classed with the dry or moist form.

The essential oils, by spray or nebulization, are also valuable in these dry forms, and are usually very agreeable.

The treatment by anatomization, since its recommendation by Jean Sales-Girons,[22] and later by Dr. Pserhofer[23] before the French Academy, has become very popular, as it deserves to be.

Solutions of chlorate of potash and permanganate of potash, and other astringent preparations, are useful when sprayed into the throat, in the forms of sore throat where the secretion is profuse. They may also be used in the form of gargles. Dr. Gabrilovicz[24] recommends inhalations of peroxide of hydrogen. I have used the peroxide, but it seems to me to be adapted to a special class of cases, or at least to serve a better purpose in special cases, where there is a tendency to the formation of a pelicle on the tonsils, or where the whole secretion is too albuminous. I like to use it as a spray in such cases, and believe its action to be similar to that of the continued action of ozone; that is, I believe it acts beneficially by dissolving the albuminous pelicle when it has been formed, and when it has not already appeared by rendering the exudate incoagulable. If this view is correct, it will be found valuable in the form of inhalation and spray in diphtheria, true croup, and those cases of tonsillitis and sore throat where the exudate contains an excess of albumin and fibrin. Yerba Reuma[25] by atomization is sometimes very valuable. Cases of croupal laryngitis (Curtin and Watson[26]), are best treated by inhalations, although atomization acts well, and the remedy should be determined, as in cases of general sore throat, by the class of inflammation, whether dry or moist. The patient should be kept in bed. Coupard and Saint Hilaire recommend a 3 per cent. solution of antipyrine in catarrhal laryngitis.

In nearly all cases where there is general febrile disturbance, I have found the use of aconite and belladonna (Ringer[27]) invaluable. An excellent protection for sensitive throats is the use of a silk handkerchief in front of the neck, in place of mufflers around it.

When all has been said, it remains to the physician to determine what the treatment in any particular case shall be, not by what the books say, but by studying the class of inflammation present, and the condition and idiosyncrasies of his patient. Then by the use of medicated inhalations and medicated sprays, the cold compress to the throat in croupal cases, together with simple gargles and some simple preparation to equalize the circulation and reduce the temperature, all these cases will recover. The minimum amount of medication that will suffice and the maximum amount of care that can be secured in nursing should be the rule here, as in the treatment of all diseases.

EARLY DIAGNOSES OF MASTOID DISEASE AND OPERATION, AS A LIFE SAVING MEASURE, IN THE PREVENTION OF PYÆMIC AND MENINGITIC COMPLICATIONS.

Read in the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY D. MILTON GREENE, M.D.,
OF GRAND RAPIDS, MICH.
Eye, Ear, and Throat Surgeon to St. Marks and U. B. A. Hospitals: Lecturer on the Eye to the St. Marks Training School: Lecturer on the Larynx and Hygiene in the Western Michigan College, etc.

Acute suppuration of the middle ear is a disease of very common occurrence, and runs its course in many instances without serious complications, ending in recovery. Other cases result in permanent destruction of a part, or the whole of the drum membrane; while some result in deafness, chronic suppuration, granulations, polypi, etc.

More serious complications frequently occur, such as suppuration in the mastoid cells, with perforation and pyæmia, cerebral abscess, or meningitis from caries and extention of inflammation.

Such complications occur more frequently, I believe, than has generally been supposed by the medical profession, and I think those who have given any considerable time to the study and treatment of aural disease will bear me out in the assertion.

The general practitioner is not awake to the dangers of this disease, and with a hypodermic of morphia, they put the patient to sleep—and the doctor as well—while the true character of the disease is masked and allowed to pursue its destructive course, resulting frequently in death, which is attributed to some other cause.

That this course of treatment has been confined to the general practitioner, I dare not charge, for I believe many otologists have been too inactive and dilatory in these cases, and prone to palliate and temporize until nature has done the work, or the disease has placed the patient in a hopeless condition; as all statistics go to prove.

While I do not wish to be understood as advocating the too free and indiscriminate use of the drill and chisel in acute suppurative otitis media, I do think we may err as far in the other direction: and I believe that the operation of opening the mastoid should be governed by the same sound surgical principles that govern other surgical operations; that we should not delay the operation until pyæmic or meningitic complications put the patient in a hopeless condition, thereby condemning the operation, and operator as well.

In looking over the literature on the subject of mastoid disease, I find no other guide to a diagnosis of pus in the cells, than the external signs and symptoms of pain, redness, swelling, and œdema over mastoid, which must be present to justify an operation; notwithstanding the report of a few cases (notably that of Dr. Knapp's, reported to this society), in which perforation, pyæmia, and death followed acute suppuration in the middle ear, without the external signs and symptoms over mastoid.

Much has been written on this subject, but it seems that we should be able to formulate some better guide to an early diagnosis than we now have in medical literature.

Pain, redness, swelling, and œdema over mastoid are not essentially signs of pus in the cells, though they do coëxist in some cases.

Though there may be cases of extension of inflammation from the antrum through the bone to the mastoid periostium, I believe it is an exception rather than the rule, and that a better explanation is found in direct extention from the middle ear along the periostium, over mastoid process.

I have seen but few cases with pain, redness, swelling, and œdema over mastoid, that have not been preceded by swelling in the external auditory canal proceeding from the tympanum, and extending over mastoid process as periostitis.

These mastoid signs and symptoms have existed with external abscess where the mastoid cells were opened and no pus found. Then why could not the converse be true? That suppuration in the mastoid cells following acute suppuration in the middle ear frequently exists, will not be disputed; but that it exists without external signs over mastoid, or pain referred to that region, frequently ending the life of its victim, I wish to emphasize by a report of five cases, in all of which a diagnosis was made, and four operations with recovery, one without operation ending in perforation, pyæmia, and death, with autopsy.

I have been able to diagnosticate this condition in many other cases where no operation was performed, some of which recovered, but more of whom died with symptoms of pyæmia—cerebral or meningitic complications, but no autopsy could be obtained.

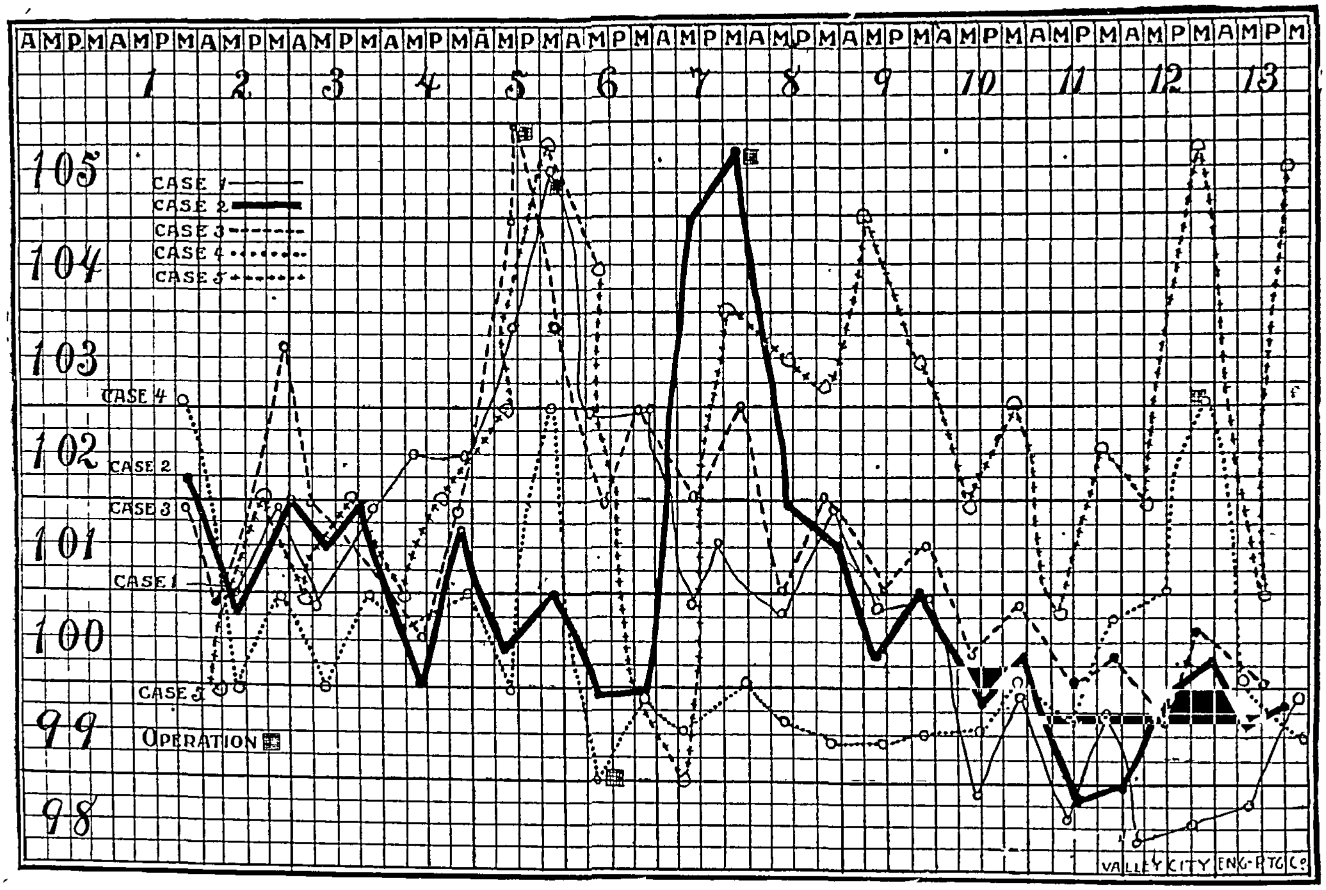
As the external mastoid signs and symptoms are not pathognomonic of pus in the cells, I think they should not be relied upon as a guide to cell complication.

The lining membrane of the Eustachian tubes, tympanum, and mastoid cells is continuous, forming an irregular cul-de-sac; and when the middle ear is inflamed we might well expect inflammation in the cells of the mastoid, by reason of structural continuity.

I believe that in all cases of acute suppurative otitis media, where pus is discharged from the ear in any considerable quantity, after the drum head is freely open and the ear has been thoroughly cleansed by irrigation with hot boracic acid solution every two hours, and Politzerization for two or three days, it must come from an abscess cavity, and could not be secreted by the lining of the tympanum; that when together with offensive discharge there is swelling and bulging in the upper and back of the tympanum, there is pus in the mastoid cells, especially when attended with rise of temperature, and pain in occipital region. When vertigo, restlessness, pain in side of head, or a sense of fullness is present it strengthens the diagnosis of cell complication, and we are justified in exposing the cells whether external signs and symptoms over mastoid are present or not.

The following five cases were those in which an early diagnosis was made, without external signs and symptoms over mastoid, followed by operation or autopsy.

All cases where pain, tenderness, swelling and œdema, or any one of them, were present, I have excluded from this report; as well as where a diagnosis was made without the external signs and symptoms but no operation, the patient afterward dying with symptoms of pyæmia, meningitis, or cerebral abscess, and no autopsy to settle the question of diagnosis.



Temperature chart of five cases of suppurative mastoiditis.

Case 1.—Mrs. B., aged 52. No previous disease of ears; July 5, had severe pain in ear from taking cold. I opened drumhead twelve hours after onset, muco-purulent discharge but little; temperature 100. Afterward temperature ranged from 100 to 101 until the fifth day, when it suddenly raised to 104.2; pulse 120. Discharge free until morning of the the fifth, but not much during that day.

Saw her at six o'clock, P.M.; temperature 104.2; says she feels pain in legs and arms more than elsewhere; no pain, redness, or œdema, or tenderness in mastoid region. Swelling and bulging from upper and back of tympanum. No swelling in external auditory canal. Membrana tympani open at back part over one-half its entire size. Tympanum full of thick, offensive pus. Opened mastoid and found cells full of pus.

Case recovered after three weeks of temperature fluctuating from 98.8 to 100. Hearing in affected ear impaired.

Case 2.—Mrs. S. V., age 24. No previous ear disease. Took cold in right ear April 2. Had ear-ache during night, and until noon of next day, when drum membrane ruptured, saw her soon after, there was some discharge of pus and mucus. Temperature 101, but soon went lower, and remained below that point until the seventh day, when with a chill the temperature went up to 104.6; pulse 110. Quantity of pus diminished, but still quite considerable. Little pain in occipital region. Had chills during high temperature. Can hear but little in left (affected) ear. Feels languid and nauseated. No œdema, pain, or other external evidences over mastoid. No swelling in external auditory canal. Membrana tympani nearly all gone. Swelling and bulging from upper and back of tympanum. Thick pus fills the canal.

Opened mastoid, found about half a dram of pus in antrum. Case recovered in about five weeks, after quite profuse sweating for some days. Hearing for voice good.

Case 3.—Miss M., age 21. Took severe cold by riding horse-back in a cold wind. Had pain in left ear that had been previously affected. Temperature 101, which, under treatment went down to 99.4, and remained until the fifth day at 4 A.M., when it suddenly rose to 104. At 10 A.M., 105, with chill and pain all over body, and some headache on left side. No pain or swelling over mastoid. No tenderness on pressure.

Operated at 11 A.M., and found cells fulls of gelatinous exudate, and thick pus. Free discharge of pus the next day. Patient recovered in five weeks. Hearing about as before the attack.

Case 4.—Mr. D. C. W., age 58; white; American. Saw this case by kindness of Dr. R. H. Spencer. Never had trouble with ears. Had always been healthy. Took a severe cold last Tuesday (seven days previous) had chills and fever. Had frequent chilly sensations. Thursday had sense of heat and fullness in left side of head. Friday nignt went to blow his nose and felt something give way in left ear, after which had some pain in ear, and at night had bloody discharge from ear. Dr. S. was called. Temperature 102.4, pulse 80, and severe pain. Membrane ruptured during night, and pain ceased. Felt well Saturday and Sunday. Temperature 99.

Monday morning at 4 A.M., had severe pain at back and top of head, which was "dull and heavy," was dizzy. No pain, redness, swelling, or œdema over mastoid, no tenderness on pressure. Drum membrane open two-thirds its size. Swelling at upper and back part of tympanum, is bulging, and looks dark and livid. No swelling in external auditory canal. Pus was flowing freely. Tongue coated and dry. Temperature 99.6; pulse 70. Nauseated and looks haggard and pinched. Ear had been irrigated thoroughly every two hours, but was soon full of pus, even in an hour or less. Odor offensive. Was there at 6 P.M., and diagnosticated suppuration in mastoid cells, and advised operating the next morning. Felt so much better the next morning that he did not go to the hospital. Discharge less, temperature 102 at 5 P.M. Aches all over, feels chills "running up and down his back." Wants the operation.

Was taken to the hospital, and assisted by Drs. Graves and Spencer, I opened the mastoid cells with chisel. When first shaving was removed the lining of cells appeared looking livid, the same as swelling in tympanum.

Pus escaped with great force when next shaving was removed. Temperature next morning 98, and remained below 100 for a week when it went up to 102.4 during day. Again gave chloroform and dug out the cells freely; found some pus. Temperature next morning 99, evening 98.4 and has never reached 100 since.

Patient feels well. Discharge free from wound, little from ear. Convalescing.

Case 5.—Mrs. ——, age 42. Was called to see this case in consultation with two of our local surgeons, on the 10th day of illness, and got the following history.

Had earache. Drum membrane was opened on second day, and some pus escaped. The case seemed to be doing well until the fifth day, when patient had a chill, and temperature of 104.8. I found auditory canal and tympanum full of pus. Swelling in right ear, and bulging at upper and back of tympanum, looks dark. Headache. No swelling or pain over mastoid. No swelling in external auditory canal. Temperature 102. Diagnosticated suppuration in mastoid cells, and advised operation; but as the other physicians did not agree with me in diagnosis, no operation was done.

About a week later was called in consultation with three surgeons with same result as before. Dr. Geo. E. Frothingham saw the case three days later, but in absence of external mastoid signs and symptoms, was of opinion that there was not suppuration in cells, but that pus had entered the jugular vein from lower part of tympanum.

I still believed if perforation had occurred it was from the mastoid cells. No operation was done, and after fifty-one days the case died from metastatic abscesses following pyæmia.

An autopsy revealed perforation into lateral sinus, and a clot three-fourths an inch long lying back of petros portion.

The viscera of body were in healthy condition. For particulars, see transactions of Michigan State Medical Society for 1892.

In conclusion would say that, in the five cases just reported, the treatment had been the most thorough in applying leeches, dry heat, blisters, etc., and in the first four, quinine had been given freely. No morphia, or other analgesic was given after the first day. Therefore the absence of pain was not due to treatment.

From a series of cases I have formed the following conclusions:

1. That in acute suppurative otitis media, with the drum head freely open—if, after two or three days' treatment by thorough irrigation with hot boracic acid solution every two hours, and the tube and tympanum cleared by Politzerization, pus continues to flow so that the canal is filled in an hour or two, or saturates a plug of absorbent cotton and attended with rise of temperature and chills without other assignable cause, with swelling and bulging of membrane in upper and back of tympanum, with no swelling from above pointing downward, and no swelling below pointing upward, there is pus in the mastoid cells, and an operation is indicated and justifiable for the safety of the patient. For, as Sir William Wild said a half century ago, "When after the first gush of pus following opening the drum membrane, it continues to flow in any considerable quantity, it must come from a pus cavity, and could not be secreted in the tympanum." (When the above mentioned signs and symptoms were present, I found pus in the cells when opened.)

2. That there is no more reason for delaying mastoid operations, when pus evidently exists in the cells, than for the surgeon to delay operation in suppurative appendicitis, or the gynecologist in pelvic abscess.

3. That the operation of opening a mastoid abscess is not more dangerous to life than opening other abscesses.

4. That if no pus is found in mastoid, it heals quickly and no harm results, but if there is pus or extreme congestion, the operation does good and may save life.

5. That the probability of death from opening healthy mastoid cells is not as great as the probability of pus existing in the cells in cases of acute suppurative otitis media, where the signs and symptoms already mentioned exist.

6. If pus exists in the cells it is a sound surgical principle that it should be removed before it has caused disease of contiguous structures.

7. That when death occurs after mastoid operations, it is from the disease for which the operation was done and not due to the operation.

8. That suppuration in the cells with early suppurative mastoid periostitis, is not as dangerous to life as where the latter does not exist, for such concomitant tends to soften the dense external bone and favors spontaneous external perforation.

9. That when swelling and tenderness in the auditory canal is extreme, so that an examination of the middle ear is difficult or impossible, it should be done under an anæsthetic.

10. That in acute suppurative otitis media, a rise of temperature to 104 or 105, with chills or rigors, does not contra-indicate opening the cells.

11. That chisels are the best instruments with which to open the mastoid, commencing at the tip of the process, and cutting upward and forward.

PERFORATION OF THE LATERAL SINUS.

While using Hamilton's bur-drill in opening the mastoid cells, at a point about a half inch back of, and on a level with, the external auditory canal, I opened into the lateral sinus at a depth of about one eighth of an inch. There was a gush of blood which I stopped by placing a finger over the drill hole; until I could secure a strip of bichloride gauze, this was packed firmly into the drill hole, and a compress and bandage applied and left undisturbed for two days.

I then removed dressings and no hæmorrhage occurred. As no pus had been reached in the first operation, I packed the drill hole with equal parts of boracic acid and iodoform, and again proceeded to open the cells with a hollow chisel, commencing at point of mastoid, cutting upward and forward, keeping close to auditory canal. I reached the cells at a depth of one-half inch, and found pus, which continued to flow freely from the wound for three weeks. In dressing the wound I always took the precaution to wash the pus out of wound with a 1 to 40 carbolic solution without disturbing the packing in drill-hole. I then replaced it with fresh powder. No bad effect followed the accident of opening the sinus, and patient made an uninterrupted recovery.

Case 5.—Mrs. W. Autopsy, by Dr. S. C. Graves in presence of Drs. D. M. Greene, G. K. Johnson, and C. H. Jonston.

Body of a woman fairly well nourished. Height about five feet and six inches. Weight about one hundred and thirty pounds. No external signs of disease except one opening and counter-opening at side of right knee made previous to death for passage of drainage tube.

A. *Thoracic Cavity.*—1. Lungs: both adherent posterior and superior portions of upper lobes to surface of chest wall. These pleuritic adhesions were not recent,showing evidence of a preceding pleuricy. Lungs, although showing considerable hypostatic congestion, were sound as far as macroscopic appearances were concerned. Portions of the mucose heavily congested. Lungs were removed for microscopic examination.

2. Heart: This viscus was normal in every respect.

B. Abdominal Viscera.—1. Stomach, pancreas, liver, spleen intestines, kidneys, and mesenteric glands, all healthy. Gall bladder contained a half dozen calculi of average size.

C. Pelvic Cavity.—1. Ovaries healthy; uterus corpus healthy; cervix had undergone induration and cystic degeneration; cysts six or eight in number, varying in size from a pea to a small marble, contained a thick glary yellowish fluid, and before being incised were very hard to sense of touch. Bladder: This organ was unopened, no evidence of trouble being present.

D. Cranial Cavity.—1. Dura mater normal.

2. Arachnoid œdematous particularly over vault and somewhat on sides.

3. Pia mater, evidently congested: some fluid in subarachnoidian spaces.

4. Encephalon, cerebrum cerebellum, pons and medulla normal.

5. Right lateral sinus as it lay along posterior border of petros portion of temporal bone, filled *with* a *thrombus*, showing evidences of suppurative inflammation.

6. Mastoid cells of right side presented evidence of a pre-existing suppurative inflammation; *mastoid* cells *and* groove for lateral sinus full of pus, and necrosis very evident; tympanum same as mastoid cells; labyrinth inflamed, no suppuration.

E. Cavity of right knee joint presented evidence of acute suppurative inflammation. Tissues undermined; areas of carious bone both on under surface of patella and on both condyles of femur. Tibial articular surfaces apparently sound.

HERPES OF THE BUCCAL MUCOUS MEMBRANE, WITH PRESENTATION OF PATIENT.

Read before the Ohio Medical Association.

BY J. E. BOYLAN M.D.,

OF CINCINNATI, O.

I have the pleasure of presenting to you this afternoon a case of vessicular inflammation of the mucous membrane of the fauces—in itself a rare condition — which I feel sure will prove sufficiently interesting to justify me in taking up a little of your valuable time. The objective symptoms are, just now, fortunately for us, very pronounced; that is, in part at least. The condition is easily seen by direct inspection, and is one which might readily be mistaken at first sight for diphtheria, or possibly for one or two other diseases which are more common in the region of the fauces. In fact, the patient states, that when diphtheria appeared in the house in which she was employed about two years ago, the attending physician—a very capable one—informed the family that she was suffering from that disease. The history of the case is, briefly, as follows:

Three years ago, in Ireland, the patient had a throat affection which began with a febrile attack, during the course of which white patches formed in her throat, which soon loosened, so that she could occasionally detach them as shreds with her tongue. The condition would improve and then get worse again—that is, more patches would form, till after some three or four months it disappeared entirely. Shortly after her arrival in this country, in September 1889, the affection broke out again and it was at that time that it was taken for diphtheria; it lasted, as upon the former occasion, several months, varying in its severity, to finally disappear entirely. In March, 1891 (a little over a year ago), the affection reoccured and it was then that she first came under my observation. When she presented herself, there was partial aphonia; she complained of pain in the throat, and of having had fever at evening for some time past; temperature at the time was 101.

Upon inspecting the pharynx I found located upon the anterior and posterior pillars, and upon the anterior surface of the soft palate, a number of circumscribed, grayish white patches. which at places amounted to a mere film, at others were thick, opaque, membranous in appearance, Upon the right side, two or more of them were confluent and besides these patches, several denuded spots were to be seen, and further, a number of punctate white specks. At first sight the condition resembled that which I had seen in tubercular pharyngitis on one or two occasions. On closer inspection, however, there was wanting the pallor of the surrounding tissue so common in phthisis of the throat and also the infiltration in the immediate vicinity of the lesion; on the contrary, the tissue about the patches was perfectly normal in appearance. Careful percussion and oscultation of the chest gave, as far as I could ascertain. absolutely negative results, and the question of phthisis, if there had been any, was altogether eliminated, in the course of a week or two, by the rapid way in which the affection disappeared at one point, after throwing off the patches to reappear at another.

The patches described, steadily increased in size, so that in a few days from the time they were first seen, they invaded the greater part of the surface of the pillars and the soft palate—the largest of them, with irregular triangular outline, extended from the middle of the uvula, to and over upon the left tonsil. At one or two places, where the membrane was thickest, it had a wrinkled appearance and loosened edges, which suggested that it might be easily detached. Upon attempting to remove it with a forcep, however, I found that in most places, it was quite firmly adherent and that the denuded surface bled upon its removal. Being, I confess, completely at a loss to account for a state of of affairs, the like of which I had never seen before, I consulted with a colleague who sees a large number of throat patients the year round, but to him too the case was as novel as it was interesting and he naturally would not venture upon a diagnosis based upon a single inspection and the history that I could give him. Microscopic examination of quite large flakes which I succeeded in detaching made by expert bacteriologists (at our city hospital) upon two different occasions, gave practically negative results. After seeing the case almost daily for over a month, during which time the symptoms had almost entirely receded and again became pronounced, I noticed that several of the smaller white spots had minute red apparently protruding centers, which suggested that they might be ruptured vesicles, and upon questioning the patient, she stated that when the condition broke out afresh she sometimes felt blisters in her mouth, which very soon broke. With this new light upon the case, I established a very close watch and instructed the patient, who was living in the house, to come to me at once when she thought that blisters had formed, and by this means I was enabled during a period of several months, to demonstrate, entirely to my satisfaction upon two distinct occasions, the presence of vesicles or blebs upon the affected mucous membrane. Upon one occasion two tense glistening blebs upon the side of the uvula — one of them the size of a split pea — upon another a cluster of five or six flatter and more opaque vesicles all of which remained upon the mucous membrane but a few hours and had disappeared after the patient had taken a meal. The condition has now lasted to my personal knowledge with the exception of three weeks in September, uninterrupted, for 13 months, and has stubbornly resisted a varied treatment including the application of astringents—of iron—of solutions of nitrate of silver and of a 50 per cent. solution of resorcine. At no time during the period mentioned was there an invasion of the posterior pharyngeal wall.

Of the vesicular inflammations which affect the buccal mucous membrane, there is but one besides Herpes known to me which includes the majority of symptoms presented in this case—namely, pemphigas and the possibility of its presence here, was suggested to me by Dr. Ravogli, who also kindly saw the case with me and who called my attention to an article on the subject by Dr. Mandelstamm in the

Berl. Klin. Woch., of last year. In works on diseases of the throat, the literature on both these subjects and especially upon pemphigus is very meager. Voltoline, Bosworth (and Cohen), ignore them both entirely. Mackenzie, Stoerck, Bresgen are silent upon the subject of pemphigus. McBride in his new work devotes six lines to pemphigus and twenty-four to herpes. More is to be learned of the throat lesions of these affections from text-books upon skin diseases, as in "Hebra's Handbuch" and the text-books of Kaposi, Neuman and Schach, but in all of these pemphigus of the buccal mucous membrane is very superficially discussed. The most thorough and detailed description of *herpes* of the mouth I have encountered in any work, is that of the ever versatile and thorough Sir Morrell Mackenzie, from which I make the following brief extracts:

"On inspection of the pharynx at the onset of the disease, a variable number of single or grouped, whitish, opaque vesicles can be perceived; they occupy the soft palate, the pillars of the fauces and the tonsils. The number of vesicles varies greatly in different cases; sometimes one or two can be seen, while in the worst instances they are arranged so closely as to become confluent. The duration of the vesicles is very ephemeral, but in many cases they appear in successive crops. The termination of the vesicular stage may take place in three different ways. In the milder cases the vesicles disappear by reabsorption and leave no lesion to mark their former situation. In another variety of the disease the vesicles burst and small circular ulcers result. In a few days these ulcers cicatrize.

In a third or severer form of the disease the ulceration takes place, *but the sore, instead of healing, becomes covered by a false membrane resembling both in appearance and structure, the exudation of diphtheria.*

These phenomena most frequently occur on the palate and are rarely seen on the posterior wall of the pharynx. When the vesicles are very numerous, the patches of exudation may unite at some places, so as to form sheets of false membrane of limited extent. In three or four days, however, the ulcers heal, the exudation becomes softened and detached and the mucous membrane recovers its healthy state." He further states that the disease is in England very rare, and that certain idiosyncracies have also been observed in patients liable to suffer from this affection; thus, "Terdieu mentions the case of a young man in whom herpes of the pharynx alternated for several years with similar eruptions of the prepuce. In one case it attacked a child for three years consecutively."

Hebra, in referring to herpes within the mouth writes as follows: "The appearance of this affection, when it attacks the skin, however, is different from that which it assumes on the mucous membrane. On the cutaneous surface this eruption consists of vesicles distended with a clear watery fluid and arranged in clusters. Within the oral cavity the affection presents different characteristics. The formation of vesicles does not go beyond its earliest stage, for the epithelium of the mucous membrane is too delicate to be able to retain, for more than a very short time, the fluid which collects beneath it. Hence the vesicles soon burst and we then perceive a number of white spots, perhaps as large as lintels' due to the maceration of the epithelium, or if this has become detached, certain shallow excoriations mark the points previously occupied by vesicles."

In considering pemphigus chronicus Hebra states the following:

"In pemphigus bullæ are sometimes found on the mucous membrane of the mouth and throat. When this is the case, the skin also is generally affected, but not invariably. It has happened that blebs have been seen on the mucus tract, while the integument remained free. It is but seldom, however, that the mucus membranes are extensively affected; much more frequently a solitary bleb appears, or a few scattered blebs, previous to or simultaneously with an outbreak upon the skin. It is indeed rather exceptional to observe on a mucus surface real bullæ—that is actual elevations of epithelium, with collections of fluid beneath them. The membrane offers so little resistance that it gives way almost as soon as an accumulation of serum begins to form. It appears as a white membranous covering which is apt to be rolled up by the movements of the tongue and finally separated and spat out." According to Kaposi the blebs or pemphigus differ anatomically from those of herpes and eczema, in that they are very superficially located, their surface being formed by the most superficial horny cell-layer, and this no doubt accounts for their early rupture and the very few occasions upon which they have been seen upon the mucous membranes. In none of the four cases of pemphigus of the mouth and fauces, reported by Dr. Mandelstamm in the article above alluded to, were blebs or bullæ to be discovered. In three of the four cases, no general eruption appeared, while under his observation. He soon lost sight of these three, but learned later that two of them had succumbed to the disease. In the last of the four the diagnosis was corroborated by the final appearance of a typical pemphigus foliaceus upon the neck, breast, stomach and hands. As the clinical picture and the course of the disease in this case, however, corresponded exactly to those presented in the other three he had no doubt as to their being identical.

This fourth case was that of an otherwise quite healthy man who, when he presented himself, complained of a difficulty of swallowing and a disagreeable odor from his mouth of several weeks' standing. The patient had at no time fever, his appetite was good, but he swallowed with difficulty, Examination showed on various parts of the tongue, cheeks, lips and pharyngeal mucous memprane, grayish white or entirely white, sharply defined circumscribed deposits, which were in places quite thin like croupous deposit, in places thicker and more compact, resembling diphtheritic membrane, and which seems pretty loosely attached; on the tongue they were confined to the free edge and under surface, on the interior surface of the soft palate the deposit became confluent to form a large grayish white membrane, from which protruded in many places red islets, which were denuded of their epithelium. On the posterior pharyngeal wall a few deposits were noticeable, the anterior surface of the epiglottis was also covered with a white deposit. The condition suggested at first mercureal stomatitis. It disappeared only to reappear in other places and lasted more than six weeks. The picture and the clinical history therefore, in these four cases of pemphigus, vary in several rather material respects from those presented in the present case. In them the lesions were scattered over a greater surface of mucous membrane and appear also upon the posterior pharyngeal wall. In herpes the lesion is confined to a comparatively small area, and according to several authors, rarely if ever extends beyond the fauces. In none of the four cases of pemphigus were vesicles to be descried upon the mucous membrane. Characteristic of all the pemphigus cases were a very offensive odor from the mouth and excessive salivation, neither of which symptoms prevail in this case. In the pemphigus cases there was at no time fever noticeable, while here as in herpes, it is ushered in with a febrile movement.

To what extent these differences are of diagnostic value I cannot presume to say.

The chronic nature of the case presented ought to be a distinctive feature, for herpes is essentially an acute affection, but there are, as we have seen, exceptions to this rule, and for reasons mentioned above, I believe that we have here to deal with a case of frequently occurring or chronic herpes, if I may use the expression.

I wish finally to apologize for having quoted so much. I did so in the hope of interesting you the more in the case. I would much prefer to show it by sunlight, but as that is not avalaible here, I will train a battery light upon it. You will find thick diphtheritic-like patches covering the pillars and the tonsils on either side, loosened in places, and even hanging in shreds, but at no point extending further back than the fauces.

If, by calling attention to this case, I shall help to throw some light upon a condition which some one of you will meet in the future, I shall have attained my object in exhibiting it.

SOME OBSERVATIONS UPON THE MECHANICAL TREATMENT OF POTT'S DISEASE.

BY A. E. HOADLEY, M.D.,
PROFESSOR OF ORTHOPEDIC SURGERY AND SURGICAL DISEASES OF JOINTS, CHICAGO POLICLINIC; AND PROFESSOR OF ORTHOPEDIC SURGERY AND SURGICAL DISEASES OF JOINTS AND CLINICAL SURGERY, COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO.

Since the introduction of the plaster jacket for the treatment of Pott's disease, it has been positively demonstrated that mechanical fixation inducing physiological rest, is competent and sufficient means in the majority of cases; and the jacket alone will fully meet these indications when judiciously applied, provided the disease exists below the middle of the upper half of the dorsal region. It is the mechanical treatment of this particular class of uncomplicated cases of which I wish to speak. I do not include those severe and rapidly developing cases that demand extension together with other means of fixation. The amount of deformity which occurs, where there has been destruction of the vertebral bodies, depends upon the number of bodies involved and the extent of destruction of each, and also upon the treatment which has been employed to restrain deformity. Upon the first condition depends all the deformity that must of necessity occur, as in nearly all cases of recognized spondylitis there must be a deformity more or less pronounced and in accordance with the extent and rapidity of the destruction. It is quite a popular idea that the deformity could have been entirely prevented had restraining treatment been instituted early enough. That opinion, which is enjoyed by a good many men of experience, is only partly true. It is true to the extent that if treatment is commenced early enough to prevent the entire destruction of a vertebral body, then deformity will not occur. But it is not true that deformity can be prevented by any kind of fixation, dressing or restraining treatment if there is entire destruction of the body of a single vertebra, then the deformity will occur in spite of treatment, and in proportion to the number of bodies involved and the extent of involvement. Deformity can be wonderfully modified, it is true, by judicious treatment, but the contraction and solidification of the new organizable material thrown out at the seat of disease will with certainty deform the column. Even though there is but a single body destroyed, the vertebræ above and below will be approximated, and the tip of the spinous process of the diseased vertebra will be tilted upwards and pushed slightly backwards, forming the prominent little nub on the back, and this without any evidence of falling forward of the upper segment of the column, or any compensating curve above or below to indicate that any other than a direct approximation of the upper and lower bodies has occurred, and the column made shorter by the thickness of nearly a vertebra. The first appearance of this little deformity makes diagnosis sure, and with the prompt application of the plaster jacket the patient goes on very comfortably, and makes a good recovery without any increase of the angular curve. So striking are the benefits of the treatment in these, the most simple as well as the most common cases of Pott's disease, that many are led to the erroneous conclusion that if the diagnosis could have been made a few days earlier no deformity would have occurred. This opinion is strengthened by the fact that occasionally diagnosis of Pott's disease is made before deformity occurs, and under prompt and efficient treatment it never does occur. In those cases with a mild and undulating character of deformity the deformity will at once be greatly modified, or even obliterated, and if not obliterated at once, it may in the course of development and corrective force entirely disappear. The foregoing statements of pathological condition have been made for the purpose of showing that the mechanical treatment should not, as is too often the case, aim at the absolute prevention of deformity, or even of correcting deformity that already exists. But its object is more, to prevent unnecessary deformity and to assist in compensation by sustaining the column through the process of degeneration and absorption of the tubercular tissue, the solidification and anchylosis of the adjacent vertebræ by means of ossification of more or less of the new cicatricial tissue, which forms in and around the seat of the disease. When we understand that with destruction of vertebræ there will come deformity, we can with much better judgment apply restraining force than we can if we expect to control deformity absolutely. The results will be better and the treatment more comfortable to the patient. As before stated, deformity must occur where there has been sufficient destruction of the bodies; but there is a class of cases where one or more bodies have been involved, sufficient to produce deformity, and still have enough left to sustain the integrity of the column under the influence of treatment, if commenced very early. In these cases deformity can not only be prevented, but that which does exist, though quite severe, can be entirely obliterated in some instances. There are many of these cases on record, but they are all cases where a considerable portion of the posterior part of the body remains intact, the disease being confined to the front of the body or bodies, or possibly the lateral aspect, in which case there will be a well-marked lateral deviation as well as backward curvature. In these cases which are more favorable for the correction of deformity, if the treatment, which must be most scientific and applied with the best skill, be delayed a few weeks, it will be of little avail—the deformity will be permanent. An indication as to the degree of destruction is found in the character of the backward curve. The sharper the angle the more complete is the destruction of the body, and the less likely to be corrected. A very acute and prominent angle cannot be obliterated. In the application of mechanical treatment in Pott's disease, at or below the upper third of the dorsal region, there are three essential points of fixation to be considered, of which two are in front and one behind. Of the two in front, one is the lower part of the column, or the pelvis, and the other is the upper dorsal spine which can be fixed by means of pressure over the upper part of the chest. The one behind is at the seat of disease and below it. If these three points are well fixed relative to each other, and maintained a sufficient time, the best possible results will follow. To maintain these three points in relative fixation is the problem. It would seem from the history of cases, and the observations of practitioners and clinical experience, that it is either not an easy one, or it is not well understood; for in the majority of cases treated with either jacket or brace, except those treated by the specialist, the support has been defective in one or more of these points. This can be well illustrated by criticising some of the jackets that we have taken off that have been applied by the general surgeon, and in fact teach a better lesson than to rely strictly upon a description of the proper application. For instance, it is common to find a jacket which will average half an inch in thickness throughout, and having been put on without being rubbed down, was not only very heavy but loose and shaky, instead of being hard and tinny in structure. Then again, the one who puts on a jacket of this character, is apt to have a misconception of the dinner pad. In consequence, one four or five times larger than is required, if one is ever required, is used, and that made to cover the entire abdomen, so that when removed the lower end of the jacket can be pulled out behind far enough to enable one to see and feel the deformity. In such a jacket there is no fixation at the lower anterior point. The upper end of the jacket is applied without due regard to the objects for which it is being put on, is usually carried up to the lower border of the axilla, and is made as high and as firm behind as in front; which is, by the way, in front especially, the weakest part of the jacket. The strongest and most rigid part is that which encircles the body opposite the disease. Such a jacket is no support to the upper anterior point where fixation should be made; and with those two points, or even one, unfixed, of what service is the jacket in the treatment? The failures, which have of necessity followed from such indifferent treatment, have led many a good man to condemn the plaster jacket and adopt some form of spinal brace for the mechanical treatment. This, of course, is open to the same criticisms, as it is applied in the majority of all cases from all sources, and especially those turned over by the general surgeon to the instrument maker for treatment, so to speak. The instrument maker places the patient in a brace which has many of the accessories that none but the artisan can appreciate. It usually consists of belt, crutches, pads, extensions and corset waist, etc., etc. In the first place the pelvic belt is made very frail for the purpose of elegance and lightness, and as it is made to encircle the pelvis between the crest of the ilium and the trochanters, it can only be efficient as a means of support for the crutches in those patients who have a good development of the hips, which is not the case with the great majority of cases of Pott's disease. As it practically gives no support to the crutches, which are intended to carry the shoulders, the chief value of such a brace, which is not much, is lost. Then again, the upright which supports the pads behind is secured at the top to the crutches by means of a strap which passes over the shoulders. This is usually the only means of securing the upper part of the column from falling forwards. The shoulders are so freely moveable that the patient is compelled to support himself by muscular action, by holding his shoulders forwards. The pads are rarely ever made to accurately fit the back. This, of course, is not a steady and uniform pressure, and therefore does not meet the first principles in the indications for treatment, namely: those of fixation and rest. When the pads are put on with springs, the apparatus is still more tiresome and inefficient. Often, in consequence of that unremitting spring pressure, the patients have been obliged to leave off the brace or have the springs removed. The only element that the broad band of elastic webbing adds, which is so often put on with the brace, is one of discomfort.

Having enumerated some of the objections to the jacket and brace as we find them applied in practice, it will be in order to suggest the simplest means which can meet the indications of treatment and obviate the errors so often made by the inexperienced. In most of the cases, especially in the early stage of the disease, the plaster of Paris jacket is the most comfortable as well as the most efficient treatment. In the later stages, when the diseased portion of the column is nearly consolidated, the brace becomes the most desirable mechanical treatment. In order to make a good plaster jacket it is necessary to have good material. Not only must the plaster and crinoline be of good quality, but the bandage must be well prepared and of recent make. It will probably not be amiss to say a few words regarding the best method of preparation. The heaviest quality of crinoline should be selected, and the bandages should be 2½ inches wide and 5 yards long. For the purpose of impregnating with plaster the finest meshes and the ultimate spaces between the fibers of which the fabric is constructed, it is advisable to wind the bandage around the hand in the loosest possible manner and secure the roll, or more properly the skein, with a safety pin transfixing the skein on one side. This should be made so loose that the plaster can easily come in contact with all parts. These skeins should be placed in a box with a tight cover, together with a quantity of plaster, and the whole tumbled for some time, which will thoroughly infiltrate the fine plaster in the cloth. To facilitate this process the box should be hung on a pivot and revolved by means of a crank. A box 14 inches square serves the purpose admirably. After the bandages have been thus tumbled with plaster, they are to be drawn through the plaster and rolled in the ordinary manner. Such a bandage fresh made will take the water very readily, and when applied it will be found to have sufficient plaster within it, to rub down smooth and solid. To properly apply the plaster of Paris jacket it is necessary to first make the bottom of the jacket, in order to constitute the lower anterior fixed point. This is done by starting the bandage across the lower part of the back, corresponding to the upper part of the sacrum. Then pass around to the front below the crest of the ilium, and down across the lower part of the abdomen, as low as possible. It very often happens that it does not go low enough. It should be drawn as tight as possible from one anterior spine to the other, and if it is made to go low enough the lower part of the jacket will be almost straight from side to side on its anterior plane in front. This part should be made very strong and heavy in front, and no dinner pad allowed to project from beneath the lower margin. As the construction of the jacket progresses it should become thinner in front and thicker behind until the seat of the disease is reached, when the character of the work should again change to heavy and very high in front, and thin and light behind above the deformity. In putting on a jacket in this way one almost instinctively puts on a figure-of-eight bandage, alternately high and low in front, crosssing the back at or below the seat of the disease, or the middle of the back if the disease be in the lumbar spine. After the jacket is thoroughly dry and hard that portion which is not strictly within the range of a figure-of-eight is superfluous, as suggested in the figure. There is no real necessity for the bandage to extend above the seat of disease behind, and the only excuse for doing so, is that it may stiffen the strong upper anterior part, which is one of the essential points of support. The abdominal portion is equally superfluous, and to the same extent. When the jacket is perfect in the essentials this abdominal portion may be cut away, but should this last be contemplated, the jacket should be constructed with that end in view, which is not advised as an uniform practice. The suggestion is more for emphasizing the principles of construction than to introduce any new thing. When the jacket is to be cut open and bound with lace-hooks it is not desirable to have a deficient abdominal portion. Since having rigidly adhered to the above principles in the application of the plaster jacket, the dinner pad has been more and more neglected, until now it is no longer thought of, and the disuse has never in a single instance been regretted. The only pad that seems to have a never failing purpose is a small, narrow and thick pad over the most prominent portion of the deformity. A pad about ½ or ¾ of an inch wide by ¼ inch thick, placed over the apices of the projecting spinous processes. This can be pulled out from above, leaving a depression on the inside in which the spinous processes can find relief from pressure. At the same time the jacket can be moulded down very close to the back and provide the widest possible surface for pressure, and on the tissues which can best tolerate it. It frequently happens, and in fact it is the common practice for the purpose of protecting the prominent nub on the back, that each side of the spine is provided with a pad. This is a mistake, for, without the pad is very thick, it wears down, and the prominent spine is the only portion in the region of the disease which touches the jacket. It soon excoriates, becomes very sore, and it has often furnished a necessity for the removal of the jacket and the addition of more padding, or cutting out a portion of the back of the jacket to accommodate the projecting spinous process. Then the surrounding surfaces of the back are not in contact with the jacket, and consequently firm and efficient support is wanting, and the additional deformity can take place. When it seems desirable to adopt the brace, the following point should be considered in addition to the principles already referred to: that is, whether or not the crutches should be used for the purpose of carrying the shoulders. Here it may be well to suggest a rule that in a general way will help to decide, although by no means is it without many exceptions. The more vertebræ involved the greater the deformity, and the more serviceable can the crutches be made. Therefore in a case which involves but a single bone, that is not progressive, it is not necessary to put on the crutches, and when not necessary they are a detriment. When several bodies have been destroyed and much deformity exists, with the suspension of the activity of the disease, and before consolidation is quite firm, it is very essential to use them. The patient will instinctively rely upon them whenever he anticipates a sudden movement or a shock of any kind. In most cases they can be dispensed with to the comfort of the patient, long before the back brace is discarded. The brace without the crutches, in its most efficient form is an exceedingly simple affair. It should consist of pelvic belt, two parallel uprights at the back, supporting a large thin pad on each side of the spine opposite the disease, secured at the top by a strap passing from the top of each upright over the shoulder and across the upper part of the chest, and around under the opposite arm to the upright of that side, and a well fitting, thin, long and narrow pad across the upper part of the chest, over which the straps pass.

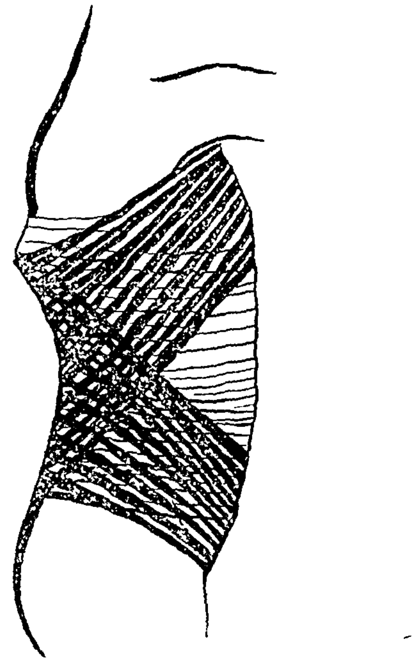


Figure 1.

The pelvic belt should be the usual light belt of

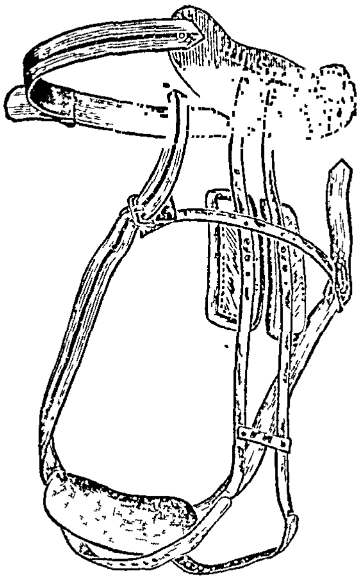

Figure 2.

steel, secured in front by means of strap and buckle; or better still, the back of the belt should be of metal and the front half entirely of leather, and made wide across the abdomen. Such a belt is only intended to keep the lower ends of the uprights in contact with the back, and not to sustain weight. The shape should be such that it will fit the back closely and allow the front part to cross at the lower part of the abdomen. It should occupy almost the same position that a well fitting inguinal hernia truss spring does. This always insures the best support, and without constricting the abdomen in the least. The uprights, two in number, should be secured to the belt by means of a hinge joint which will allow the belt to adjust itself, and pass up the back, parallel, one on each side of the spine, to nearly the top of the scapula, where they should diverge until the upper ends correspond to the junction of the upper surface of the shoulder and the neck, about one inch below it. They should be secured to each other by means of a cross piece of metal at the point where the upper ends begin to diverge, and opposite the tenth rib there should be another cross-bar secured to the upright, made long enough to reach the posterior axillary line when it has been shaped to fit the body. To each end of this cross piece a buckle should be secured, at proper angle, to receive the strap that comes over the shoulder from the top of the opposite upright. Throughout the entire length they should accurately fit the back. In order to accomplish this it is necessary to take the shape of the back on each side of the spine by means of the strip of lead, and transcribe the shape on paper to make a working drawing. The patient should be sustained in as straight a position as possible while the form is being taken. The drawing should also show the exact position of the belt in its relation to the uprights as to angle, height, etc. The pads should be thin, lightly padded and made to fit the surface accurately, and cover as large an area as practical. When the pads are secured to the uprights, it will set the uprights back away from the body, the thickness of the pads at that point, and perhaps double that distance at the upper ends, which is quite sufficient to prevent any unpleasant contact, and secure at the same time a very close fitting brace, with room enough to provide for compensation at the top. From time to time both uprights and pads can be easily changed in shape for the purpose of readjustment. The chest pad can be made of wood, hard rubber, or thin metal, brass being the best of the metals, and easiest of all materials to work. Thin brass can be hammered to fit readily, and then it retains the small studs or buttons well, which are to hold the straps in place. Hard rubber is perhaps the most elegant material, but it is much more troublesome to handle. The upper central part of the pad should rest upon the sternum just below the sternal heads of the clavicle. The upper margin of the pad should slope each way from the center downwards and outwards in a groove below the clavicle and in front of the shoulder, to nearly the lower margin of the pectoral muscles. This groove is bounded by the clavicle and shoulder joint on the upper and outer side, and by the thorax on the lower and inner side. It can be appreciated to an advantage by having the patient with bare chest before you, and with the tips of the fingers trace the groove while the patient is making moderate forward and backward movements of the shoulders. In this way one can readily appreciate the exact position for the upper margin of the pad. This should be traced with a pencil and paper pattern cut to fit. The pad, in the average case, should be about two inches wide, and therefore, when complete, it is somewhat crescent shape. This shape will be found to vary greatly in different patients. The padding should be thick and rounded at the upper and outer parts of the pad, thin and flat below and in the center. The round upper margin can be hammered on when the brass plate is used. In any case, where a metal frame for the pad is used, it should be hammered enough to give it stiffness. The upper margin of the pad should be provided with a post button on each side, corresponding to the uprights, and the lower outer margin or angle on each side should also be furnished with a button. The straps which pass over the shoulders are to be provided with button holes, as close as they can be conveniently made, for the purpose of buttoning on to the chest pad. After the strap has been buttoned to the top of the pad, it may be found more convenient for the strap to pass to the lower button of the same side and then to the cross-bar where it buckles, than to cross to the opposite side as before suggested. Or it may be thought more convenient still to have short straps attached directly to the lower outer angle of the pad to buckle to the cross-bar, and then, of course, the straps attached to the upper ends of the uprights would be short—simply long enough to button on to the upper margin of the pad. In consequence of the rolled and thickened upper margin of the pad, there is a strong tendency for the lower angle of the pad to tilt out, so that in the adjustment of the lower end of the strap it is only necessary to have it tight enough to hold the pad in even contact with the chest. It will then be found that the greatest tension is on the straps which pass over the shoulders. This very simple and inexpensive apparatus, with the proper adjustment of the straps, will sustain the convalescent patient very comfortably and securely, and at the same time not so rigidly but what the patient can, by the slightest movement of the body, relieve any particular point from pressure momentarily, which makes firm corrective pressure tolerable. It also provides for each of three points for fixation, very efficiently.

The reasons why this apparatus is not desirable in the early stages of the disease, are because it permits a greater range of motion of the body, and it is not as comfortable to sleep in, and consequently should not be put on until it is safe to allow the patient to sleep without any apparatus whatever. The jacket furnishes not only the best possible fixation but maintains a greater amount of body quiet and that with the greatest comfort, and it is not uncomfortable at night. When it seems best to use the crutches a very different form of pelvic belt should be constructed. A piece of heavy leather from 2½ to 4 inches wide cut so as to lay flat on the back and then pass around forwards and downwards to the bottom of the abdomen with the upper margin of the leather extending at least an inch above the crest of ilium. This should be thoroughly wet and a wedge shaped piece removed from the upper edge of the leather over the crest, then it snould be accurately moulded and fitted, and the margin of the notch where the wedge shaped piece was removed, closed with stitches. After it has been thoroughly moulded to the form including the crest of the ilium, it should be bound to the patient until it is dry, about six hours. It can then be removed and it will retain the shape of the body. It should then be reinforced with the usual thin belt of steel, which by the way, need not pass farther forwards than the anterior superior spine. The front of the leather is to be trimmed down on its upper margin to an inch or an inch and a half in width, and provided with a lacing of three hooks. To the steel portion of this belt is to be attached the crutches as well as the uprights at the back previously described, which, by the way, should be made from one to two inches longer, as with the use of crutches the shoulders are carried considerably higher. The amount required can be readily estimated by shoving the patient's shoulders up while the measure is being taken. The attachment of the crutches should be by means of a rivet which will permit of forward and backward motion. The ordinary extension bar should be used and the upper or crutch end left perfectly free; no straps before or behind; no elastic webbing around the body or across the abdomen. The belt just described can be fitted upon any patient no matter to what extent the deformity has progressed; there will be sufficient crest found if sought for, over which the leather can be moulded to insure perfect and competent support for the shoulders and this is all that we expect to do with the crutches. In the average case such a pelvic belt will, with ease to the patient, support the whole upper part of the body. It is not tiresome; it does not excoriate. It is not expensive and should always be used when, for any reason, it is desirable to have support from the pelvis. During the last few years the brace has been elaborated into a most complex combination of adjunct bars, supernumerary pads, rachets, rack and pinions, set screws, adjustable extensions, lock and swivel joints, levers, compound and simple, springs of all kinds before and behind, and hinges both false and real, all in graceful proportions with finished and elegant workmanship, ornamented with fancy leather and embroidery until the general surgeon, at least, looks upon one of these highly wrought and elegant instruments with bewilderment, and it is the general surgeon who treats the greatest number of cases of Pott's disease. He knows very well that he has not given time enough to that department of mechanics to suggest any changes, so with the statement that there is nothing too good for his patient, the elegant incumbrance is ordered and the application and adjustment left entirely with the instrument maker.

Thus it comes, and it seems a strange assertion to make, that as the brace has developed in multiplicity of parts and elegance of construction it has deteriorated in usefulness in the hands of the general surgeon. Many an opportunity has been improved to examine patients, both in public clinic and in private practice, who have been enveloped in one of these elegant complexities, and we could demonstrate in most cases that they were absolutely useless. They were made and put on by an instrument maker who works according to certain drawings and rules and he does his best by putting in all the parts as near as possible in the right place. Then he puts it on, which is all he can do. Why it is a failure he does not know, and why should he? Neither does the surgeon, and why should he not? That is the question the solution of which has been the excuse for this paper.

Venetian Building.

UVULOTOMY.

Read before the Section of Laryngology and Otology, at the Forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY CARL H. VON KLEIN, A.M., M.D.,
OF CLEVELAND, O.

The most common and the most frequent operation of the throat the laryngologist is called on to perform is excision of the uvula; yet, with all the modern inventions of uvulotomes and with its various methods, none seem to have been devised so as to perform the operation of uvulotomy so the uvula could perform its functions in all its physiological intentions and purposes the same as in a normal condition.

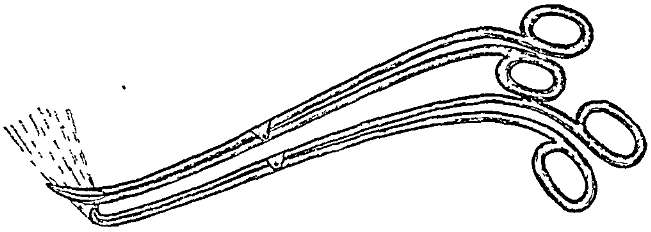
To the people in common it matters not how the operation is performed, as long as it is not cut off too much and the tickling in the throat has ceased. But to the professional man of voice culture, to the singer and the elocutionist, it is a vast difference, as upon the organs of the throat they depend mainly for the existence of a livelihood, the same as the laborer depends upon his hands. Especially the singer, who exhibits his attainments and purity of sound sometimes under the most critical observation, upon which his entire reputation may rest.

A singer with a defective uvula will always exhibit a falsetto. The voice and its degrees of pitch may be accurately executed by the individuals notwithstanding the deformity. Yet, the upper notes are too variable, under the accidental influence of muscular effort, to be the mechanical cause of the fixed and accurate degree of scale. For, when any point of pitch is maintained, the soft palate and its appendage, the uvula, is impaired to a movement that will affect the voice. The change in the palate consists of a convulsive action of the uvula which cannot be performed with one that is stumpy. Again, a stumpy uvula cannot perform the functions of lubricating the soft palate and its kindred organs.

An excision of the uvula, once performed, can be recognized during man's existence, the same as in an amputated finger. When he opens his mouth and makes the sound "ah" the stump contracts and forms a concave bottom.

To overcome the old methods I have devised a curved scissors which cuts the uvula, beginning at the front, and ends upwards back, leaving it delicate and pointy at the bottom, with which a vocalist can perform all the functions of the uvula, the same as within a normal condition.

Not only to avoid the impediment in the singer is my method practical, but in every way I prefer it to the straight scissors. For when the uvula is cut off with a straight scissors it is much harder to heal than with the curved. The food passing by the uvula keeps it constantly irritated, and in many cases it takes a long time before it is thoroughly healed.



The cut I here exhibit is in the back part of the uvula, hence the food passing by does not come in contact with the cut surface.

In speaking the cut surface does not rub on the tongue to produce irritation, consequently it heals readily in a period never longer than ten days. I particularly desire to call your attention to the bloodless ablation of the uvula, by taking hold with long forceps, stretching the uvula downwards, outwards, and cut it at the place where first focused. When the excision is made it contracts, and no blood is visible, as though it was ligated. In sixty-four obscissions in the manner I here describe, all were bloodless.

PURULENT BRAIN DEPOSITS, AND PHLEBITIS AND THROMBOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

BY FRANK ALLPORT, M.D.,
OF MINNEAPOLIS, MINN.,
PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLOGY IN THE UNIVERSITY OF MINNESOTA, ETC.

(Continued from page 558.)

Case 84.—New York Medical Journal, June 12, 1886. Treated by A. Mathewson. Male, age forty. Right ear. Chronic otorrhœa; pain over mastoid; Wilde's incision; brain complication. Death.

Autopsy—Caries of tympanic roof. Abscess of brain over tympanum.

Case 85.—New York Medical Journal, June 12, 1886. Treated by A. Mathewson. Female, age eleven. Left ear. Chronic otorrhœa; middle ear, polypus; spontaneous opening in external mastoid plate; facial paralysis; improvement; later became worse; pain; vomiting; drowsiness; constipation; optic neuritis; convulsions. Death.

Autopsy.—Dura-mater adherent to petrous bone. Pus in cerebellum.

Case 86.—New York Medical Journal, June 12, 1886. Treated by A. Mathewson. Male, age five and one-half. Right ear. Acute otitis media; drum-head not perforated. Death.

Autopsy.—Caries of roof of tympanum. Basilar meningitis.

Case 87.—British Medical Journal, 1887, No. 1363, page 317. Treated by W. S. Greenfield. Male, age twenty-six. Left ear, Deafness; headache; vomiting; ptosis of lid; optic neuritis; sub-normal temperature. Semi-comatose.

Diagnosis.—Abscess of temporo-sphenoidal lobe.

Operation.—Skull trephined; dura-mater incised; pus found; irrigation; drainage. Recovery.

Case 88.—Canada Lancet, November, 1881. Treated by G. S. Ryerson. Child. Left ear. Scarlet fever; acute purulent otitis; mastoid pain; swelling and tenderness; pain in head; ptosis of right eyelid; divergent squint of right eye; both pupils dilated. Coma; mastoid opened; pus found; improvement; later, became worse; vision poor; optic discs swollen; fever; delirium. Death.

Autopsy.—Dura-mater adherent to skull. Pus on surface of both superior lobes. Purulent thrombi in lateral sinus.

Case 89.—Archives fur Ohrenheil, Vol. 26, page 1. Treated by Wagenhauser. Acute otitis media. Left ear. Mastoid operation. Death.

Autopsy.—Purulent meningitis. Inner plate of mastoid carious, and perforated. Inner surface of petrous bone covered with extensive granulations.

Case 90.—Archives of Otolgy, January, 1891, page 1. Treated by Harry Friedenwald, of Baltimore. Male age seventeen. Left ear. Chronic otorrhœa; had an abscess lanced behind his ear years ago; pain and dizziness; aural polypi; left-sided deafness; chills; headache; some fever; tenderness behind ear. Later, chills and high fever.

Operation.—Von Bergmann's landmarks were followed, viz.: from a point 4 cm. behind the external meatus, in a line made with the lower margin of the orbit, ascend perpendicularly for 5 cm. to reach the point for trephining. No pus. The mastoid was then opened and pus and cholesteatoma were found. Death.

Autopsy.—Pus in the pia-mater covering the surface of the left frontal and parietal lobes. Perforation of inner mastoid plate. Purulent thrombus in lateral sinus.

Case 91.—Archives of Otolgy, 1879. Treated by T. M. Pierce. Female, age thirty-four. Left ear. Chronic otorrhœa; hard swelling in front of ear; granulations in meatus, concealing necrosis; pain in left cheek and parietal bone; left facial paralysis; pain in vertex and occipital region; carious bone discharged from ear; meatus very carious; later, the entire area of disease had fallen in, comprising the external meatus, up to the level of the drum-head, exposing the temporo-maxillary articulation; later, condyle of the ramus of the jaw now exposed; later, the area of disease was now almost large enough to admit the closed fist; hernia cerebri appeared; later, paralysis of right side with aphasia; constipation. Death.

Autopsy.—It is not necessary to detail the destruction of bony and other tissues. It was terrific. Even the aqueductus Fallopii, the semi-circular canal, and the carotid canal were exposed. The temporal bone presented a circular aperture through which the tip of the temporo-sphenoidal lobe protruded.

Case 92.—Transactions American Otolological So-

ciety.—Treated by S. Sexton of New York City. Purulent otitis media; caries of the attic, antrum, and tympanum; lymphadenoma; facial paralysis. Death.

Autopsy.—Inner wall of attic gone, leaving the semi-circular canals exposed. Caries of antrum and mastoid cells. Purulent meningitis.

Case 93.—American Otological Society, July 30, 1887. Treated by Roosa, of New York City. Male, age eleven. Right ear. Painful swelling over ear; abscess opened; no fistula. Death.

Autopsy.—Abscess in temporo-sphenoidal lobe. Encapsulated. Drum-head perforated. Upper meatus necrotic. At junction of mastoid and squamous, necrosis was present. Meatus and mastoid cells filled with caseous pus.

Case 94.—Medical Times, 1885, Vol. 2, page 395. Treated by Parker. Male, age six. Chronic otorrhœa. Abscess above ear; opened; coma; convulsions. Death.

Autopsy.—Necrosis of the floor of the middle temporal fossa, corresponding to position of middle ear. Adhesion between brain and dura-mater. Perforation of dura-mater. Abscess in temporal lobe. Mastoid cells filled with cheesy debris.

Case 95.—Archives of Otology, March, 1884. Treated by T. G. Sutphen. Male, age forty-four. Both ears. Chronic otorrhœa; acute exacerbation; pupils contracted; aphasia; seventh nerve on left side paralyzed; choked discs both eyes; necrosis left external meatus; paralysis right arm and leg; an opening was made into the cranial cavity by way of the meatus and mastoid, but no pus was found. Death.

Autopsy.—Abscess in anterior and middle lobes of left hemisphere. Encapsulated. Necrosis of petrous.

Case 96.—Archives of Otology, March, 1884. Treated by T. G. Sutphen. Male, age twenty-one. Right ear. Chronic otorrhœa; acute exacerbation; paralysis of right abducens muscle; sight impaired in both eyes; swollen discs both eyes; fever and chills; coma; probe can be passed into cranial cavity by way of upper portion of meatus; no pus. Death.

Autopsy.—Thrombi in right lateral and superior longitudinal sinuses. Caries in the sulcus for the lateral sinus. Necrosis of superior surface of the petrous. Caries of meatus, tympanum, and walls of mastoid.

Case 97.—Archives of Otology, June, 1881, page 121. Treated by S. Moss, of Heidelberg. Male, age twenty-three. Left ear. Chronic otorrhœa; polypus; paralysis of left facial nerve; total deafness left ear; vertigo; coma. Death.

Autopsy.—Abscess in left cerebellum. Encapsulated.

Case 98.—Archives of Otology, March, 1894. Treated by A. Hedinger. Male. Left ear. Acute purulent otitis; fever; fluctuating; swelling of left parotid gland; opened; found pus. If swelling is pressed, pus may escape from external meatus; coma. Death.

Autopsy.—Much pus under dura-mater and arachnoid. Purulent thrombus in superior petrosal sinus. Ulcer in this sinus communicating with the pyramid. Carious opening connects cranial cavity, tympanum and mastoid antrum. Ulcer in transverse sinus. Pus in antrum and tympanum. External meatus carious.

Case 99.—Archives of Otology, March, 1894. Treated by A. Hedinger. Female, left ear. Acute purulent otitis; fever; polypus; removed; granulations; swelling of glands below ear and frequent attacks of pain in the entire left half of head; vertigo. Death from tuberculosis.

Autopsy.—Ex. meatus carious. Tegmen-tympani carious. Between bulbus venæ jugularis and bony portions of Eustachian tube, there were two fistulæ leading into the pyramid. Tympanum carious and purulent. Internal wall of carotid canal is carious. Thrombus in carotid artery. Mastoid antrum filled with cheesy pus.

Case 100.—Archives of Otology, June, 1885. Treated by Herman Rothholz. Male, age twenty. Right ear. Chronic otorrhœa; pain in vertex; deaf; drum-head gone; polypus; partial paralysis of auditory nerve; temperature and pulse fairly normal; constipation; stupor; delirium; unconsciousness; divergent strabismus; herpes on right cheek. Death.

Autopsy.—Dura-mater congested. Purulent leptomeningitis, especially at base. Communicating abscess in right cerebellum. Encapsulated. Drum-head gone. Pus and polypus in tympanum. Ossicles gone. Chorda-tympani destroyed. Fallopian canal full of pus. Facial nerve lies exposed in tympanum. It looks normal as it passes through the tympanum, whilst from the gangliform swelling to the internal auditory meatus, it is inflamed. The acoustic nerve presents the same general appearance. Pus in vestibule and cochlea. The petrous bone is saturated with pus.

Case 101.—Archives of Otology, December, 1886. Treated by T. G. Sutphen, Newark, N. J. Male, age twenty-five. Right ear. Chronic otorrhœa, resulting from a blow on the ear. Four years before coming to Sutphen, had an abscess behind the ear, which was opened, and healed; swelling recently recurred with pain; meatus swelled; tympanum filled with granulations and has carious bone; abscess opened, and communication with tympanum established; improvement; later, the conditions became re-established in a more aggravated form; a fistulous opening existed just below the external meatus, through which pus escaped; carious bone in this fistula; water injected into the meatus escaped into the mouth and fistula; later, vomiting; headache; aural hæmorrhages; fever; pain; delirium. Death.

Autopsy.—The bone in the region of the middle ear had been changed into one large carious cavity. Opening into internal carotid artery. Cerebellum abscess communicating with carious cavity.

Case 102.—Archives of Otology, March, 1880. Treated by Thomas R. Pooley. Male, age thirty. Right ear. Chronic otorrhœa; pain in right ear and right side of head; swollen and tender mastoid; deaf: Wilde's incision; carious bone was found; trephining refused; chills; delirium; mastoid opened: pus found: coma. Death.

Autopsy.—Meningitis at convexity and base. Red inflammatory softening at apex of temporal lobe. Pus in pia-mater and arachnoid. Upper surface of cerebellum inflamed. Pus in tympanum, mastoid antrum and cells, vestibule, semi-circular canals, Eustachian tube, and canal for tensor-tympani. Necrosis in tympanum. Incus and stapes gone.

Case 103.—Archives of Otology, June, 1887. Treated by Barr and McEwen of Glasgow. Male, age nine. Right ear. Chronic otorrhœa; acute exacerbation; mastoid abscess; opened; found pus: no improvement; fever slight; ptosis of right eye; paresis left internal rectus and left orbicularis-palpebrarum;

veins right side of head congested; right mastoid muscle rigid; pain on pressure of position of vein which passes through the posterior condyloid foramen; dense stupor; pulse slow and feeble. Constipation.

Operation.—General anæsthsia; thorough antisepsis; skull trephined one and one-half inches above and one-half inch behind the centre of the external meatus; dura-mater opened; dura-mater and pia-mater congested; a hollow needle was inserted toward the eminence of the petrous bone; pus found, three-fourths inch deep; the skull was at the same operation again trephined in the base, just above the osseous boundary of the external meatus, involving the squamo-petrosal suture; the abscess was reached; irrigation; chicken-bone drainage tube; antisepic dressings. Recovery.

Case 104.—Archives of Otology, September, 1889. Treated by William McEwen of Glasgow. Male, age seventeen. Left ear. Chronic otorrhœa; unconscious; weak and slow pulse; optic neuritis; nearly moribund; carious sinus into mastoid cells; vomiting; pain in head; chills. Left hemiplegia-

Operation.—Mastoid opened; carious matter expelled; lateral sinus exposed, on which he found granulations; the bone was then perforated further back than the groove for the lateral sinus; pus escaped from over the cerebellum; chicken-bone drainage tube; antiseptic dressings. Recovery.

Case 105.—British Medical Journal. November 8, 1879. Treated by Thomas Barr of Glasgow. Male, age seventeen. Left ear. Chronic otorrhœa; vomiting; pain in head; stupor; tremors; convulsions. Death.

Autopsy.—Left temporo-sphenoidal lobe adherent to the bone beneath. Abscess in temporo-sphenoidal lobe. Encapsulated. Two carious openings in petrous bone. One in the tympanic roof; the other in the groove for the lateral sinus, communicating with the mastoid cells.

Case 106.—Glasgow Medical Journal, July, 1880. Treated by Thomas Barr of Glasgow. Male, age fourteen. Left ear. Chronic otorrhœa; vomiting; pain; coma; spasmodic contraction of flexors of arms and legs. Death.

Autopsy.—Abscess in temporal lobe. Drum-head gone. Polypus in tympanum. Stapes gone.

Case 107.—Glasgow Medical Journrl, July, 1880. Treated by Thomas Barr. Male, age seventeen. Left ear. Chronic otorrhœa; aphasia; constipation; unconsciousness; paresis of right side; coma. Death

Autopsy.—Abscess in left temporal lobe. Carious fistula in roof of antrum. Carious opening in sigmoid flexure. Carious opening in posterior upper wall of ex. meatus. All the fistulæ communicated with the mastoid cells.

Case 108.—Glasgow Medical Journal, July, 1880. Treated by Thomas Barr. Male, age twelve. Left ear. Chronic otorrhœa; pain in mastoid and occiput; chills; vomiting; constipation. Death.

Autopsy.—Pus beneath dura-mater on posterior surface of left petrous bone. The walls of the left lateral sinus were thickened and detached from the bone by underlying pus. Mastoid cells filled with cheesy pus.

Case 109.—Treated by Remmel. Right ear. Chronic otorrhœa. Medium temperature and pulse; pain in head and neck. Œdema and tenderness over mastoid; later, right facial paralysis; œdema of right upper eye-lid; delirium; anæsthesia right half of face; diarrhœa. Death.

Autopsy.—Caries of tympanum. Thrombus in right lateral sinus. Phlebitis of jugular vein. The thrombus in the lateral sinus extended through the inferior petrosal sinus to the right cavernous sinus, thence through the circular sinus to the left cavernous sinus, which was filled with disorganized clots and pus.

Case 110.—Treated by Taylor. Chronic otorrhœa; delirium; strabismus; diplopia; sudden rise and fall of temperature; retinal veins large and tortous. Death.

Autopsy.—Thrombosis of lateral sinus. Thrombosis and phlebitis of jugular vein. Abscess in lungs.

(*To be continued.*)

HYPNOTISM IN ITS RELATIONS TO MEDICAL JURISPRUDENCE.

Read before the Medico-Legal Society of Chicago, October 1, 1892

BY MR. E. O. BROWN,
OF THE CHICAGO BAR

I can hope to do little more than call your attention to the importance of the interesting subject which I have undertaken to discuss to-night. No one can realize better than I, how entirely inadequate my presentation of it must be, because of the limitations of time, and opportunity for preparation, in the midst of occupations which are continuously engrossing. If I can awaken an interest which shall result in a discussion between my learned brethren of the two faculties here present, I shall have accomplished quite as much as I dare expect.

That the subject *is* an interesting one, I think no one can truly deny. Within a little more than ten years an entirely new factor has been introduced into the problem of legal responsibility. A physical, or perhaps, more properly speaking, a psychological state, with which neither the laws, nor the lawmakers of any people have concerned themselves; the existence of which, indeed, they have never seemed to know, has been discovered to exist. It is a state which is neither sanity nor madness, and neither sleeping nor waking—as these terms are generally used. In it, a person must be considered as irresponsible for his words, his thoughts and his acts; and yet, in it he has all the exterior characteristics of a person fully awake, reasonable, and master of himself. This is startling enough by itself, and to deal with it properly, would require machinery very different from that by which our courts now endeavor to determine questions of sanity and insanity. When to this proposition is added the further one, that a person in the hypnotized state of which I speak, becomes frequently an automaton in the hands of his hypnotizer, and that an action, good, bad or indifferent, suggested by the hypnotizer to the subject, will, in a large proportion of cases, be carried out by the subject after waking, however abhorrent it may be to his natural character, and carried out frequently after an interval of many days, weeks, or even months, the imagination itself finds it difficult to grasp all the complications in social and legal relations to which it may give rise.

How recent is all the knowledge which we have upon the possibilities of the hypnotic state, is a fact within the personal observation of all of us here.

When I was in college, only twenty-five years ago, I remember well that I knew both a natural (as the term was then used) somnambulist, and one in whom the state was regularly induced for therapeutic purposes.

The first was a class-mate, who upon many occasions, in his sleep performed strange and fantastic actions, which became widely known among his college friends. A peculiarity often remarked upon, was his complete recollection during one sleep-walking adventure of that which had taken place in a previous episode of the same nature, and his complete forgetfulness during his normal waking state of either. But I do not remember that even in a community of students, who would naturally be supposed to be interested in such matters, the how or why of this double personality—for in effect it was nothing else—was ever discussed.

The second case was much more notable, and did provoke, among the limited circle which was acquainted with it, much wonder and curiosity. It even, I think, found its way into the work upon mental philosophy of the late Dr. Wayland, President of Brown University.

A young girl in Providence, named Winsor, had suffered through accident a serious injury to her spine. She became bedridden, and for a number of years, and until her death, remained so. At first she suffered terribly from inability to sleep, and although sometimes falling into a comatose condition, anything like true rest was impossible to her, until it was found by her physician, that certain manipulations by himself on or about her head, removed the nervous restlessness which was always present, but increased at the coming of night—and threw her first into a more cheerful and quiet state of mind and body, which passed afterward during the evening, into a comparatively quiet sleep. But almost contemporaneously with this discovery and its practical application, came strange mental and physical phenomena. The right hand and arm of Miss Winsor were, in her normal state, paralyzed. In the condition into which she was thrown by the doctor's manipulations (a condition which is now familiar enough to investigators and experimenters in hypnotism under the name of the "hypnotic trance," or sometimes "induced somnambulism"), this arm and hand became capable of use and, indeed, the more efficient of her members. Another strange thing developed itself. Her manner and disposition changed in the hypnotic state. Her capacity for various kinds of handicraft was wonderfully increased in this induced condition over that which she possessed in her normal state. She seemed to have greater vigor, vitality and energy; and in this induced state, and for many hours during each evening, she would draw, make fancy work, and do many other things for which she felt no disposition and no sufficient strength during the day. And finally she developed a personality in the somnambulistic state as distinct as possible from that of her daily life. Of all the acts done and experience suffered during the day she had a perfect memory nightly; and she also recollected everything which had taken place on preceding *nights* and in her secondary state—while during the day she was as entirely oblivious of everything which occurred between the times of her being put into the hypnotic state and her waking in the morning, as healthy persons are of that which takes place about them while they are in a sound sleep.

This case was one which lasted through many years; the physician in attendance being kept by it, to the detriment of his own health, constantly at home, for it was found that it had a very serious effect upon the condition of his patient if any other physician attempted to fill his place, and induce the hypnotic or somnambulistic condition, which had become to the patient her only method of rest.

I have spoken at length of this case, which came under my own immediate and very frequent observation, simply to emphasize the difference between the condition of medical knowledge upon the subject then and now. The condition of Miss Winsor was a marvel—hardly credited by those unfamiliar with it. Frequent charges of imposture were made against her, and her physician, whose devotion to his patient through long years is entitled to the greatest possible admiration, was viewed, because of his simple narration of undeniable facts, with suspicion and dislike by some of his professional brethren, who should have known far better.

But all this is changed. To-day it is as easy to refer the case of Miss Winsor to a well-known class or category of pathological conditions, as that of an ordinary fever patient. All the peculiarities of her state have been duplicated and reduplicated hundreds, and indeed thousands of times. That which was in her case the result of disease, has been shown by experiment to be capable of production in persons of normal health, but of peculiar sensitiveness to so-called hypnotic influence.

And the hypnotic state into which such persons have been thrown has been analyzed, tested, and one might almost say dissected—not, of course, to anything like a complete knowledge of the subject, but to a wonderfully increased and developed one.

Twenty years ago the world did not believe in hypnotism. In 1866 Dr. Liebault, today one of the most noted names in all matters of this nature, published a book called "Sleep and Kindred States of Being," in which he set forth certain theories, which have since been almost universally accepted—and but six copies were sold. There had been, of course, for an hundred years, an acquaintance by medical men with the so-called phenomena of animal magnetism. The French Academy of Sciences published a report concerning Mesmer—partly charlatan, partly mystic and partly scientist—but there was so much during the years which followed of undeniable quackery, mixed with the so-called mesmeric, or magnetic phenomena, that it was not until such men as Charcot, Bernheim, Beaunis, Richer, Richet, Janet and others known to the world to be the greatest of living neurologists, took up the subject, and eagerly pursued the fascinating inquiries that it suggested, that enough unprejudiced and unashamed interest was awakened in other scientific minds to bring about any considerable increase of definite knowledge upon the subject. But to day, although it is in France particularly that the study of hypnotism is pursued systematically, and its therapeutic uses acknowledged and enforced, yet to the men who are constantly carrying on and pressing the investigation at Nancy and at Paris, at Havre and Bordeaux, the whole medical world, as I understand, looks, at least with respect, if not with deference; and there is little skepticism as to the results which they have achieved, and but little dissent from the propositions upon which they agree.

It is true that great differences of theory exist between the so-called rival schools of Paris and of Nancy. Dr. Charcot and his colleagues at Paris—Janet, Binet, Ribot and others, hold that hypnotism is a pathological condition produced by peculiar and extraneous action upon the nerves, and style it abnormal. The doctors at Nancy, upon the other hand, represented by Bernheim and Liebault, and other great names, entertain the view that there is nothing abnormal about hypnotic sleep; that it is normal sleep hypnotically produced, and produced entirely by suggestion. They say that hypnotism is not a pathological condition, but a psychological state, and that all the extraneous machinery used by the Paris school in inducing it are mere signs to the patient of what is expected of him, and that the fact that hystero-epileptic patients are more easily hypnotizable than healthy persons, means simply that they are more suggestible.

So as to the value of hypnotic suggestion in curing diseases, trifling or serious; and as to the matter with which my paper is more particularly concerned, criminal suggestions, or suggestions affecting legal rights and relations, there is serious and grave controversy between men of equal repute, and of equal opportunities and capacities for observation. I do not by any means intend to venture to-night upon a discussion of these disputed questions. I am not so presumptuous as to consider my opinion valuable to this company, nor is it within the scope of the purpose with which I prepared this paper. But, as I have above indicated, certain things are agreed upon by these mentioned investigators. And these things upon which there is no longer controversy, are sufficient to establish the importance of the suggestions which I purpose to make concerning the relation of hypnotism to medical jurisprudence.

The propositions then upon which there may be said to be substantial agreement, are concisely, as I understand it, as follows:

By various methods, most of them, at least, involving some fixation of vision, and resulting in nervous fatigue, coupled with more or less authoritative actions or command on the part of the hypnotizer, a very considerable proportion of persons upon whom the experiment may be tried without their resisting it, can be thrown into a hypnotic state; that is, into a state of induced somnambulism, in which, like the Winsor girl, of whom I have spoken, they can think, speak and act—their eyes are open, and they present the appearance of a waking person, and yet to a greater or less extent they are irresponsible and, apparently, indeed, of a more or less different personality from their usual and normal one. This state is induced in the subjects experimented on or therapeutically treated at the hospital of La Salpetriere, at Paris, simply by directing the attention of the eyes by an upward and inward squint upon some bright object held slightly in front of and above them, while a few passes of the kind familiar to most of us as magnetic, or mesmeric, are made on or in the vicinity of the head—or else, pressure is used upon the eyeballs or at other points on the head.

At Nancy, on the other hand, the state is generally induced by a rapid rotary and alternating motion of the patient's fists before the eyes, coupled with extremely imperative commands to sleep.

It is only a portion of the persons upon whom the attempt to hypnotize is made who can be to any extent brought under its influence, even though they profess to be willing; and it is a much smaller proportion who are, in the language, of the French savants "tres bonnes somnanbules" that is, to a high degree "suggestible"; and therefore, the persons to whom the criminal suggestions are made of which I purpose to speak, could be of much danger.

Prof. Liegeois, of the law department of the University of Nancy, and an eminent authority upon this matter, belonging too to the school of investigators which sees the most danger in this matter of possible criminal suggestion, calculates the number as 4 out of 100 in any given community. But, as he well remarks, inasmuch as this in the city of Paris alone means 100,000 persons, the percentage is not insignificant. In certain classes of people, of course, greater amenability to the influences described is to be found than in others. Thus, hystero-epileptic patients are made by the physicians of Paris almost the only subjects of their experiments—so much more readily do they respond, in their opinion, to the suggestions which are made. But it is quite certain, nevertheless—and from this the Paris school does not dissent—that it is by no means *necessary* in order that a subject may turn out to be "unetres bonne somnambule" that he or she should have any symptoms of hysteria or epilepsy. Women are more susceptible than men; children than adults.

Dr. Berillon, in a recent paper before the Psychological Congress, just held in London, insists that eight out of every ten children from six to fifteen years of age, no matter how robust and healthy, are susceptible of being sent into a profound sleep after the first or second attempt. And this was his conclusion after experiments upon 250 children of both sexes, taken from all classes of society.

After one successful attempt has been made by a given operator upon a given subject it is constantly easier, if the subject still continues to submit to the experiment, for the hypnotizer to induce the desired condition. And, in a very short time, if the person is a good subject, very slight suggestions of what was originally necessary to produce the hypnotic condition, will be sufficient to throw the patient into a trance.

And for this result, with those who have been often before treated, it has been thoroughly proven at La Salpetriere that fifteen seconds are sufficient. Or rather the inducement of the state is instantaneous—a quick command—a clap of the hands, is sufficient. The quarter of a minute will suffice for the production of the hypnotic state, the suggestion of some act thereafter to be performed, and the awakening. The awakening of the subject is generally effected by blowing upon the eyeballs.

Many strange things. not within the purview of this paper, can be predicated of this hypnotic state. But that which I am about to set forth, although I would scarcely dare to call it in the bewildering variety of results which have been attained—the strangest, is the one to which alone I would direct your attention. It is that the hypnotizer can, during the continuance of the hypnotic state in his patient, suggest to him the commission of a given act, hours, days or weeks, indeed, ahead, and that suggestion becoming a fixed idea will, in the case of the good subject—certainly be committed by him after his awakening—as surely as a stone dropped from the hand will fall to the ground. Nor is the state in which he performs the act that of *apparent* somnambulism. In the hypnotic state proper, or in the ordinary hypnotic state, the subject is passive to a greater or less extent. Although, as I have said, he can think, speak and act, he thinks, speaks and acts mostly by excitation from without. He has more or less the appearances familiar in somnambulists. But the awakening seems to be thorough. Before that time arrives for the commission of the suggested act, he is apparently in an entirely normal state. But when he commits the act, and thus realizes the suggestion which has been made, one or several hours, or several days it may be, in advance,—although he must certainly be, so the authorities agree, again in a hypnotic state in the largest sense of the word,—he has, for all who see him walk and speak and act, the appearance not of a somnambulist, but of a man fully awake. Nor will the person committing the act, *until he is again placed in the hypnotic trance*, remembar that any suggestion has been made to him. He may strenuously deny it—all that he may know is that he feels toward the commission of the act an absolutely irresistible impulse.

I have sufficiently indicated, I think, by this statement as to the conditions which bring about, and which follow from the hypnotic trance, the ways by which it may touch in many points, legal and social relations. It is true that in France, where this subject of the relations of hypnotism to medical jurisprudence have almost solely been treated, the dispute waxes hot as to how far actual crimes of a serious character have been or are likely to be, the result of criminal suggestion made by a hypnotizer upon his willing or unwilling subject. But all the authorities from Charcot down agree as to the possibility, and admit a certain danger—how *great* that danger may be, is the only point concerning which they differ.

The school at Nancy are inclined to a pessimistic view of the matter; they of Paris, to a much more cheerful opinion. Certain it is that criminal suggestions have been made to many of the subjects of the professors and doctors at Nancy, which have been in appearance carried out to the letter, precaution, of course, having been taken against actual bad results.

Thus, one patient of good character was caused, by suggestion, to place the muzzle of a revolver close to her mother and fire upon her—not knowing that the pistol was not loaded, and having every reason to suppose that it was. So too, a powder, which a patient was told was a poison, was administered by him to his aunt; and numberless cases of small theft for the purpose of experiment have been suggested, and in every instance carried out. But Charcot and the Parisian school rather scoff at the value of these experiments. They by no means suggest imposture or simulation—the character of the experimenters and the nature of the experiments entirely forbid this; but they call these criminal actions, "laboratory crimes," and insist that they bear but little resemblance to actual ones. The arguments which they use to sustain this proposition, are, after all, somewhat obscure. It seems to me that there is in them a suggestion that they are afraid that adhesion to the propositions advanced by the Nancy school concerning them would unduly alarm the public. And yet, it is hard to say, so strange is the action of the human mind, conscious or unconscious, that the lingering knowledge that things are not what they seem to be, does *not* remain in the hypnotic subject, as the Parisian doctors urge.

Professor Baldwin who has recently visited La Salpetriere and Nancy, and written most interesting letters therefrom to the *New York Nation*, says that repeated experiments at Nancy have shown that a man to whom the suggestion has been made in a hypnotic state will stab a covered figure in bed, which has been represented to him as a living man, and which he believes to be so. The doctors at Nancy say if their confreres at Paris do not believe that this criminal suggestion would be equally efficacious, if the stuffed figure were a real man, let some one of them take the place of the stuffed figure. According to Prof. Baldwin, the Parisian doctors reply that until the jealousy of them by the Nancy school grows less, they must respectfully decline the experiment.

But, seriously, it is the *amount*, and not the reality of the danger concerning which the doctors disagree; and in the matter of lesser crimes, such as offenses against female virtue, smaller thefts, and particularly the bearing of false witness or perjury, it is admitted by all that the danger is very real. Especially is it urged by Dr. Berillon, the editor of the *Revue de l'Hypnotisme*, although a stanch member of the Paris school, that children, from their very great suggestibility can easily be made, in the hands of conspirators, the most dangerous of false witnesses. It could easily be seen too, how in such matters as testamentary wills the ends of justice and right may be defeated. Undue influence—a familiar term to our law, gains a new meaning in the light of what has been set forth.

And here I wish to make a digression for a moment. It may be that there are those here to whom hypnotism and the researches which have been made concerning it, by the ablest investigators, physiological and psychological, of the world, are not well known, and who look in a paper like this for some argument that hypnotism and its results as shown in the subjects experimented upon, are not simulation and imposture. I wish to say to them that I do not purpose to make any such argument, I have simply assumed it as indubitable; nor have I thought it at all necessary to cite cases, or advance proofs, of which the literature of the subject is full. In the present state of medical science, I should have no fear that any physician would here advance the contrary proposition. But I am not so sure of the lawyers, if their attention has never been called to the phenomena of which I have been speaking—for the law, I shall take occasion to say again in my paper, is not progressive, and lawyers are far from open-minded, as a rule, to the marvels of science. The fact is, that years ago the theory of simulation upon the part of the subjects of hypnotism was given up by all intelligent critics. All sorts of surgical operations have been performed where hypnotism has taken the place of anæsthetics. Muscular conditions absolutely impossible in the normal state have been induced in thousands of cases. Cures by suggestion at La Salpetriere and at Nancy, and indeed all over the world, have been made in myriads of cases. Indeed, the characteristic look of the hypnotic patient would, if the up-rolling of the eyeballs were simulated, imply nothing less than a world-wide conspiracy. But all bodily symptoms excluded, a complete proof would be afforded by the ever growing improbability that thousands of persons in hundreds of places, guiltless of theories, and unacquainted with each other, could build up by their several acts of conscious or unconscious deceit a large and consistent body of psychological results. To any person who doubts the reality of the phenomena which the various hypnotists of the world—many of them among its most famous and eminent physicians, agree are the concomitants of the hypnotic trance, I can only say that I advise him to make some acquaintance with the present literature of hypnotism, say in the proceedings and journals of the Society of Psychical Research, that wonderfully pains-taking and scientifically-minded body of which the Honorable Arthur Balfour is a leading member, and of which Professor James, of Harvard University, has written so enthusiastically in a late number of the *Forum*.

To return to the connection of hypnotism with medical jurisprudence, it is not only in connection with "laboratory crimes," such as I have spoken of, that in France the discussion of criminal suggestion has been waged. You, doubtless, all remember how, without success, the defense of criminal suggestion was made in the case of Gabrielle Bompard, the accomplice of Eyraud, in the terrible murder of Gouffe,—Professor Liegois still insists that there was grave injustice in that trial. However, that may be, the doctrine has not always been so unsuccessfully put forward. According to the system in use in France—much better arranged than here for determining the responsibility or irresponsibility of persons accused of crime, many cases of automatism, so-called, natural or suggested, have been referred to the properly authorized medical officers in charge of various departments of the Police of Paris and of France, and in several reported cases, their report having fully established to the satisfaction of the court the abnormal state of the prisoner when the offense was committed, he was discharged.

It is not strange that in a country in which hypnotism received its first scientific investigation, and where research and experimentation have gone to such lengths as they have in France, there should have been much more thought and said and written of its possible relations to legal rights and judicial proceedings, than in any other country in the world, And there is another reason, too, for this. It is undoubtedly true that a larger proportion of the mercurial and nervous and excitable French people is amenable to hypnotism and hypnotic influences, than of more phlegmatic races. And I must confess that up to the present time there does not seem, so far as the record of legal proceedings in England and America goes, much occasion for that alarm which has manifested itself among the ablest physicians and lawyers of France, in the matter of possible criminal suggestion. But it is impossible that to France alone and to French physicians alone the scientific inquiry into hypnotism will be long confined. Already in this country we have, not whole schools of physicians indeed, but individual (and very clever) men eagerly pursuing this line of inquiry. The knowledge of the possibilities which lie within the range of induced somnambulism will soon make rapid progress among the masses of the people, and it can hardly be expected that we shall enjoy, therefore, long in the future, an immunity such as now seems to exist from the dangers which have been so forcibly suggested in France. Nor is this a thing to be regretted or deprecated, for the knowledge which is to be gained is knowledge, after all, of the truth, which in the end can injure no one. If hypnotism can be used for bad purposes, it can and undoubtedly will be used much more for good ones. There is no powerful and beneficent drug which is not also a poison, with the power of destroying as truly as that of healing. And at all events, whether newly discovered truths are to be welcomed or deprecated, it is necessary to arrange one's life, and to organize society according to them when they are known. And it is but the part of cowardice to say that there are any truths which should not be known.

It will be long, however, I think, before we shall need to attend to any such extreme suggestion as that which has recently been put forward in France by no less an authority than Prof. Liegeois—called by him "moral vaccination." He has seriously proposed that to boards of competent practitioners commissioned by the Government—as in the case of vaccination in this country—all persons, and especially all children, should be brought. If they are found non-suggestible, well and good; but if they can be hypnotized and brought to a profound degree of "induced somnambulism," there should be made to them, in that state, a suggestion that thereafter *it* shall not be possible for any other person, by any other means, to hypnotize them. For precaution, it is proposed that this shall be renewed from year to year. For such a suggestion that the patient is not to succumb to the hypnotic influence of any other person than the one making to him, or her, this suggestion, has been found to be equally efficacious with any other.

I say that we need hardly anticipate that such a proposition as this will ever be made and considered seriously in our time and environment. But unless the law and its professors are prepared to be justly reproached with that want of adaptability to the changed conditions of life and states of human knowledge which has been too frequently their share in the past, it *will* be necessary, and that in the near future, to consider carefully the question of the responsibility or the irresponsibility of persons claiming to have been the subject of irresistible suggestion.

It is not in the abstract doctrines of our law that the difficulty will be found; it is in the present conditions of their application. We have seen that spontaneous somnambulism is a highly analogous state to the hypnotic trance; and as to spontaneous somnambulism, there is authority already in the law for saying that, as the somnambulist does not enjoy the free and rational exercise of his understanding, and is more or less unconscious of his outward relations, none of his acts during the paroxysms can rightfully be imputed to him as crimes. Courts would undoubtedly hold that, considering the abrogation of self-control peculiar to the physical condition of the somnambulist, no moral or legal responsibility could be attached to his actions. And indeed, so far as the law can be said to be formulated at all concerning the criminal responsibility of an insane person—as it was formulated, for example, by Sir James Stephen in his draft of a criminal code for Great Britain—there is found in it a rule which, properly applied, would meet the theoretical difficulties which might arise from the phenomena of hypnotism. An insane person, according to this formulation, is not to be held responsible for an act which he may commit when his mental disease prevents him either, *a*, from knowing the nature of the act done; or, *b*, from knowing that it is forbidden by law; or, *c*, from knowing that it is morally wrong; or, *d*, from controlling his own conduct.

In class (*d*) the hypnotic subject of criminal suggestion would fall. His mental state would prevent him from controlling his own conduct. But, it goes without saying that when a practical application of this rule was sought to be made there would be, under present conditions, and in the present state of the law in relation to expert testimony,—an absolute impossibility of determining to the satisfaction of the public at least, whether in any given case the accused was at the time of any criminal act in the condition named. We know now, how utterly absurd, nay, indeed, how indecent are the scenes in court when the question of responsibility, as depending upon mental condition, is to be decided by a jury. Experts, so-callled, who are the retained partisans of one side or other in the controversy, are brought in troops into court, where their testimony is thrown into hotch potch. There is hardly a proposition advanced by one so-called expert that another is not found to deny. The jury are absolutely without any valuable test by which they can determine the respective weight to be given to the different and conflicting witnesses. Those experts who are the most entitled to credit are generally the most modest, and reserved and cautious in their statements. They are, consequently, the favorite target for the insults and abuse of counsel.

Such a flagrant scandal has this come to be in our criminal insanity trials that there are no decent lawyers who do not now deplore the system which prevails. But for all that, they are very slow in suggesting change. It seems as if the spirit in which the English lawyers replied to would be law reformers from Rome 500 years ago—"Nolumus mutare leges Angliæ;" "We do not wish to change the laws of England" live yet in bench and bar. Averse to change as lawyers thus are, it would be useless under our system, by which the body of the law adapts itself slowly and painfully and in adjudicated cases only, to new conditions, to attempt to formulate new rules, or new theories of legal responsibilty, because of the new knowledge we have of hypnotism.

It will only be in contested cases that any departure from, or in addition to present formulas will have their origin. And we may be sure that it will be slowly and painfully *enough* that any such change will come about.

But, in the practical conduct of all trials which involve an inquiry into mental responsibility, it is not hopeless to look for a change in the immediate future. This change is one extremely needed, and it may be brought about. as I believe, by the vigorous effort of such societies as this. It is a reform which is needed, without reference to the new and perplexing problems which hypnotism may throw upon upon courts and juries, but it is one which the possibility of such problems serves to accentuate and emphasize.

It would only need, in one of our criminal courts, a war of experts upon a subject so little investigated and understood in this country as hypnotism, to cap the climax of the absurdity of such judicial farces as have already been enacted when mental alienation was the subject of discussion.

I propose then, and this is the only practical application to which I would bring my paper, that some such system as this in regard to expert testimony should be urged upon our law-makers. Let each state appoint an Examining Board of genuine experts upon mental and nervous diseases and abnormal states. Certainly, in communities like ours which support and officer asylums for the insane, it would not be difficult to make such a Board of competent and honorable men. Let one of the duties of that Board be to testify as experts upon any cases submitted to them, for which their compensation should come from the body politic. Let houses of detention be established, to which shall be committed before trial all persons for whom the plea of mental irresponsibility is urged. There let such persons be examined. Let them there also, should occasion seem to demand it, be thrown into the hypnotic state for examination. Let the examination be made more or less prolonged, according to the necessity of the case, as certified by the Board of Examiners. Then, after the examination is completed, let the *depositions* of these real experts be taken, away from the highly unscientific atmosphere of a criminal trial, but upon direct examination and cross examination. Let these depositions thereafter be used *before the court* to determine the question of responsibility.

By such a plan, it seems to me, we can make a great and urgently needed improvement in the administration of criminal justice, and not only remedy the abuses which now exist, but provide against their further development when into the practical domain of our court trials, and legal investigations, shall come the new and perplexing problems of hypnotism.

Discussion.

Dr. Sanger Brown:—I can only express the opinion I have formed upon the subject of hypnotism from what I have learned by reading and listening to those who have had experience of the phenomena. I have witnessed many attempts to hypnotize people, but none of them were successful.

Granting, however, that the asserted facts are true, it would seem to me to accord with the evidences of psychology to assume that to be a good hypnotic subject implies instability of the intellectual centers; that is, weak cerebral tissues. For instance, when we are willing to trust a member of our community with money, we express our confidence in the high quality of his cerebral tissues; various areas in his cerebral cortex have received certain impressions, and these have become firmly correlated in a manner which will surely prompt him to act in conformity with the principles of honesty. In this way the various elements of character may be traced out.

Now, it is generally conceded that during childhood and youth these impressions and the correlating connections between them have not yet become quite established, because the tissues have not yet fully developed, and allowances are made by courts of law in such cases. It is also generally conceded that among adults instability of the cerebral centers is much more common in women than in men.

When we wish to induce a person to pursue a certain line of action we attack his cerebral centers, and just in proportion to the vigor of our attack and the stability of the centers will we succeed. We may even dose him with alcohol to temporarily reduce his resistance.

Now, it is well known that by far the largest proportion of the population who are thus open to influence, persuasion or suggestion is found among the women and children, and it is asserted that from this same class comes the hypnotic subject. Without discussing in this place the fine points of difference between what is commonly designated persuasive influence and the phenomena of hypnotism, I wish to assert that in their medico-legal relations they are, in my opinion, very nearly alike, both having an operator and a passive subject; the passivity of the subject depending upon the deficiency of his cerebral tissues in both instances, and the law needs to make no special provision for one more than the other.

There is practically no probability that a normal adult can be hypnotized unless he wants to be, and this being the case, I do not think that hypnotism should be accepted by the courts as an excuse for crime.

Judge Richard S. Tuthill:—This is my first evening with this Society, but I intend that it shall not be my last, because I find here an opportunity for instruction that it seems to me should be improved by members of my profession, and more especially by those occupying as I do at the present time a judicial position. These questions are not only interesting but they are of intense practical utility, and I think it is the duty of the lawyer and the judge, as well as of the medical man, to study and endeavor to master so far as he can the more practical questions such as have been disdussed to-night.

I would like to say a few words on the subject of expert testimony, to which Mr. Brown referred, and his suggestions as to a remedy for the abuses which prevail in expert testimony in sane and insane cases in our courts, and the legal and moral responsibility of persons charged with crime. I had one quite noted case in which medical men of eminence came on the witness stand and gave very diverse testimony. I allude to the trial of Mrs. Rawson for the attempt made by her upon the life of the lawyer of her husband. I don,t think there was very much difference of opinion among the medical men who testified as to the real condition of the person charged with the crime, but there was a disposition on the part of the jury, which is very often found, to seize at any kind of a chance to reach an acquittal, she being an interesting woman and having suffered what seemed to the ordinary observer many wrongs and hardships. I do not see how it is possible to adopt the suggestion made by Mr. Brown and have certain witnesses furnished by the State, and say that others shall not testify. Such a thing, it seems to me, would be impracticable if not undesirable. But I think a society of this sort can do a great deal in getting up a proper *esprit du corps* in the medical and legal profession, so that there shall be a desire on the part of every medical man who goes on the stand to have mastered his subject so that he can speak with an authority that will be recognized, because when there is knowledge and certainty of opinion, I have observed that influence goes with it.

The case of John Redmond, who murdered Dr. Wilder, was tried before me. There was not very much difference of opinion among the medical gentlemen who testified; some said he was insane and the others did not disagree with them, they said that at times he was insane, that is his mind was disordered. There the law comes in and says to what extent this disorder should go to make a man legally and morally unaccountable. It is not every disordered intellect that is acquitted of crime in the law. I think the rule of the law is just, fair and intelligent; it is not every man who is not sane that is to be acquitted and turned at large on the community; it is only where insanity has gone to such an extent that it sweeps away his reason and understanding and he has no more control over himself than a mad dog that he is to be held unaccountable. When Dr. Dewey, who had had charge of John Redmond, came on the stand without fee, which fact I took pains to have brought out before the jury, I had every confidence in his character and intention to tell the truth. I asked him whether he believed that John Redmond at the time he fired the shot which killed Dr. Wilder knew that he was doing a legal and moral wrong, and he said that he did. And the law held him responsible; the jury held him guilty of murder and fixed his penalty at imprisonment in the penitentiary for life. I believe if the gentlemen of the medical profession who are called upon to testify upon this subject would draw that distinction and would insist that although a man may have a disordered intellect, although he may be erratic and have illusions to a certain extent, yet if he knows the difference between moral and legal right and wrong he should be held responsible, there would be fewer of these scandals in the courts, of which Mr. Brown speaks.

Mr. E. O. Brown:—The statement of the Judge rather surprises me that in all civilized countries the condition of things prevails which prevails here. But it does seem to me that the system which prevails in continental countries is worthy of consideration because of the effects it brings about in the examination of mental alienation. My idea, which I tried to express in my paper, is not to limit simply expert testimony, but to have certain experts picked out for the purpose who should be impartial, and that would necessarily limit them. We should not have a system which makes the expert witnesses who are testifying upon matters of scientific investigation, partizans of one side or the other of the controversy. That is the essential part of the proposition which I made. It seems to me it is possible to disjoin the investigation of a question of fact or occurence from the investigation of the mental condition of any given person. As to the rule which the Judge lays down about insanity, it strikes me that he is a little inconsistent; if the question is only whether a man knows whether his action is right or wrong, then the other test which he suggested of an uncontrollable impulse, must be excluded because insane persons do know that a thing is wrong sometimes when they are unable to control their conduct and not do the thing. The Judges in England stated to the House of Lords, in the McNaughton case, that the true test was whether the criminal knew the difference between right and wrong. But that has since been much departed from here and in England, and everywhere because the question is, sometimes, whether knowing a thing to be wrong the person committing the crime could control his own action.

Dr. Archibald Church:—During the past three years, practically without any definite intention on my part, I have had more or less to do with this subject of hypotism and have in a rather desultory way experimented with it at not infrequent intervals. I would say that the proportion of people hypnotizable is less than that laid down by the essayist of the evening upon the statement of European authorities. I have been unable to hypnotize as many as 4 per cent. although I have tried to select my cases with more or less care, picking out those whom I thought might be fit subjects, and not wasting my time upon those who would resist it from natural causes or inclination. That hypnotism is possible goes without argument; that crimes may be due to hypnotism I think is in all probability equally a fact. Dr. Bernheim, who has been quoted this eveding, on one occasion in Paris went into the various hospital wards where he selected hypnotizable subjects and made suggestions after this order: he would tell them that on a certain occasion at a certain place and certain hour they saw a crime committed and he would detail the incidents of the crime and also tell them they would be called before a magistrate and asked to testify. In the next ward he would give the same suggestions from a little different standpoint, and in that way hypnotized several witnesses, being careful not to tell any one of them exactly the same story, so that the appearance of collusion would be eliminated. The next day these men were brought before a judge and each told the story suggested to him with all the circumstantial details necessary, had the facts justified it, to produce a conviction. In other instances insignificant crimes have been committed upon hypnotic suggestions, and that a serious crime might be committed I think must be admitted. But it is to be kept in mind that extremely few subjects are so hypnotizable that a deliberate crime after a considerable lapse of time could be carried out by them even if it had been suggested.

If it were not another story, I would like to take up this question of legal and moral responsibility and the right and wrong test which has been laid down in the McNaughton case and has been servilely followed by the legal profession ever since.

I wish in closing to call your attention to some resolutions adopted in 1876 by this Society, strongly advising against all public demonstrations of hypnotism.

Dr. D. T. Nelson:—I am interested in this subject but I confess I don't know anything about it and I am very much of the opinion that those who know most about it know very little. I am very much obliged to the essayist for giving us so much of his research, experience and suggestion.

Dr. E. J. Doering:—Some ten years ago I felt a good deal like Dr. Sanger Brown about hypnotism. You will recollect that a member of the Chicago Medical Society made some interesting experiments before the Society on half a dozen subjects. A little later I was one of a committee to investigate the subject and it was found that they were all so-called "horses." But after witnessing some extraordinary experiments last year in Charcot's clinic at Paris, I am very much interested in the subject as illustrated in the admirable paper presented by Mr. Brown to-night.

I also want to say a word about expert testimony. I most cordially agree with Mr. Brown, and I think physicians as a rule, outside of those who are particularly interested in expert fees, feel very much as Mr. Brown does, that, wholly independent of the fee, the ends of justice would be more quickly served.

Dr. Samuel J. Jones:—I am too unfamiliar with the subject to express any opinion in regard to hypnotism, and I can only say as far as expert testimony is concerned, that it is a matter which appeals to all in the medical profession as well as in the legal profession. I feel that we cannot advocate that question too much until we obtain a point more definite, more satisfactory, approaching more nearly to justice both to those concerning whom testimony is given, and those who are called upon to testify.

Dr. D. R. Brower:—I have made, in the last eight or ten years at Chicago and elsewhere, a good many attempts at producing this hypnotic state that the essayist has so admirably described, and I am free to confess that I am not an expert in the hypnotic art. I have found an exceedingly small proportion of people who could be brought into this condition, and this proportion among native born exceedingly small. The only really good subjects I have ever succeeded in finding were among the French, and not our Canadian French, but French from France, and they have been almost always females. There is something peculiar about the construction of the nervous system of a Frenchwoman that makes her to a very much larger degree susceptible to this influence that I have never found among our own people; indeed, I have rarely, if ever, succeeded in producing the hypnotic state in a native American unless it happened to be a child of twelve or fourteen years of age and then I had very great doubts as to the genuineness of the performance, so I don't believe there is any such cause of alarm as would seem to be indicated by the paper. I think the proportion of negroes who are susceptible to this hypnotic influence is very large, greater even than the French, and it may be that there is danger of suggesting crimes to them. Where a person is susceptible to hypnotic influence, I believe it is possible to make suggestions to them of a criminal character; and I am well aware of another fact, that if you have once succeeded in inducing this hypnotic condition it is an easy matter to repeat it, and the more frequently it is repeated the easier it is. So I think that while the French may have reason to be alarmed, so far as we are concerned in this country there is not much cause for fear.

Upon the question of expert testimony, I quite agree with the essayist, I think we have some of the most disagreeable presentations of questions at courts that can be imagined. Just what the remedy is I don't know, it may not be in the direction he has suggested, but certain it is that our methods of expert testimony, so-called, are a disgrace to the medical profession. I am free to confess that I differ most emphatically from the definition of responsibility that my distinguished and personal friend, Judge Tuthill, has given us. I think there must be something more, something very much more, than the mere knowledge of right and wrong to establish this question of responsibility. The insane man may know perfectly well the difference between right and wrong and yet commit a criminal act and not in my judgment, be responsible for it. The narrow limits of responsibility that were set up in the McNaughten case will not apply. In scientific psychiatry there must be the power to do what is right as well as the power to know what is right, there must be power as well as knowledge.

Judge Richard S. Tuthill:—I do not think I disagree with the chairman very much in his idea; I think that people are insane who really know the difference between what is legal right and legal wrong, but I think such people should be restrained and that they should be held accountable for their actions, not on their own account, but on account of the community.

Mr. E. O. Brown, in closing the discussion, said: I don't know that Judge Tuthill and I disagree so much if we could only eliminate the unnecessary part of what each of us has said. I thoroughly agree with him that it is not every man who is in an abnormal state of mind that should be acquitted of crime if he be put upon trial for that crime, and the crime is proven to have been committed by him. It does not seem to me that the mere fact that his mind is disordered should be sufficient to acquit him. But the trouble in Judge Tuthill's argument is in limiting the state of mind which should acquit him or which should prevent his being stigmatized as a criminal, to his knowledge of whether the act was right or wrong; now I doubt whether that is true. The deliberate opinion of the very high authority in English law in the McNaughton case was that that was the test, and that alone; but I do not think it is presumptuous to say that that rule has never given satisfaction to the lawyers or the bench either in England or America, and has been thrown aside—not absolutely denied, but not followed, and treated with very much less consideration than one would suppose a rule enunciated by such high authority would be in a profession that follows precedents so closely as does the law. Most of the acquittals—and I think Judge Tuthill will agree to this—of persons in this country and England, upon the ground of insanity, have been where the real question was that of uncontrollable impulse, or impossibility to control the conduct, rather than the want of knowledge of right and wrong.

As to the matter of hypnotism, I was very much pleased to hear what has been said about it by the physicians, and I should have liked very much to have heard something more about Charcot's clinic, because it has always seemed to me that these experiments conducted in Paris under Charcot's immediate supervision, have been the most convincing of any of the phenomena that hypnotism has presented. I quite agree with our presiding officer that the danger of criminal suggestion is not so great here as it is in France, but it does seem to me that with the extension of knowledge among all classes of people as to the possibilities of hypnotism, and the fact that we have among us a population not Anglo-Saxon but largely Celtic, and that we have a negro population which is very amenable to such influences, and that children of all races are peculiarly susceptible, makes it necessary, not that we should become panic stricken about it, not that we should take any extreme measures, but that we should look carefully at the rules and practices which prevail in our courts, in order that we may reform those things which are present abuses, and which will be abuses of more importance and of more far-reaching bad results if these problems of hypnotism are to be thrown upon the courts. That is the connection which I made between this matter of expert testimony and the main subject of the paper. It seems to me that we do not now have to propose any practical measures to ward off the dangers of hypnotism, but to consider that there are new questions of responsibility to add to the perplexities which the courts already suffer from in the matter of alienation; that we ought to be looking about to see whether the rules and practices which now prevail are according to right and reason, or whether they can be improved upon; and I must say that the medical profession ought to take very advanced and energetic action in this matter, because—with regret I say it—the lawyers never will.

SECTION ON PHYSIOLOGY AND DIETETICS.

RECORD OF MINUTES.

TUESDAY, JUNE 7.

The Section met at 3 P.M., Dr. Kleinschmidt in the chair. On motion the Section adjourned to meet on June 8, at 3 P.M.

WEDNESDAY, JUNE 8.

Section called to order 3:30 P.M. Records read and accepted.

The Chairman then delivered his address on "Physiology," culling from publications in many languages the progress made during the year. which was very remarkable and of intense interest, for the contributions shed new light on functions and some of them,—especially as to the cerebellum were revolutionary in medicine.

The thanks of the Section were voted to the chairman for his unusually able and timely resumé.

Papers also were read as follows: On the Navy Ration by Assist. Surgeon C. A. Siegfried U. S. N; on the Marine Ration by Dr. G. W. Stoner, Marine-Hospital Service, and on The Army Ration by Assist. Surgeon C. E. Woodruff, U. S. A. The thanks of the Section were accorded to these gentlemen through the Secretary.

The time consumed was about three hours and then the Section adjourned to 9 A.M., June 9.

THURSDAY, JUNE 9.

Met at 9 A.M. Discussion of the Army, Navy and Marine Rations.

The Secretary said that he was in favor of testing foods singly fed with water, tea or coffee as drinks, flavored or not with lemon juice,—under military or naval discipline, in order to get at the best foods for the service. Assist. Surgeon Seigfried said that nothing could be done with soldiers or sailors outside of the rations more than with civilians unless they volunteered and were paid extra for it.

The Secretary thought that a wheat sausage would be far better than the famous "peasaussage" of the German Army, a sample of which had been submitted to the Section by Assist. Surgeon Woodruff, as well as another sample of American make which was deemed inferior. The reason is that men can live on wheat alone with the above drinks for 45 days, it is said, and suffer none in health, while on peas the time was only ten to 15 days. He asked if the government would consider the use of such a wheat sausage if submitted. Dr. Siegfried replied he thought not, and that nothing could be done over and beyond the regular list of foods. This was a singular statement since the government is all the time experimenting with new armaments, and good foods are the best armaments.

The Chairman then said that he thought the present rations were perfect, and that "peasausage" was merely to tide over sudden emergencies when the armies were to be cut off from their base of supplies. The Secretary replied that so far as he could learn, the cause of camp diseases was not the bad air (malaria) but food, such as hard tack, for example. The evidence to support this view was a series of experiments made by another, in feeding men exclusively on hard tack, coffee and water alone—which experiments showed that in ten days, at least, camp diarrhœa was caused in all the cases with varying severity. Now the way to upset this was the very simple one of repeating the experiments, and it seemed to the Secretary that if the laws prevented military or naval tests in this direction, the laws should be changed to allow it. We want healthy soldiers and sailors. The standard of health is found in the morphologies of the blood, sputum (if any), urine and feces of a healthy infant nursing a healthy mother's breast. This standard the Secretary got in adults by diet. So in the proposed military or naval experiments these morphologies should be recorded and the results estimated from them.

The Secretary said that he thought that a diet of ⅔ animal and ⅓ vegetable would be the best army ration, from the fact that all puerperal women thus fed thrived and had a plenty of breast milk. The main facts of this idea are brought out in a book, "*Food in Motherhood*" published by David Stott, London, Eng., to which reference was respectfully made as showing the honest intentions of the writer.

Dr. Siegfried said that such experiments only could be made outside in schools or universities. The Secretary thinks the subject so important that the Government should authorize the military and naval staffs to form such schools.

The Secretary wished to thank the government officials, *i.e.*, Surgeon-General Sutherland, of the Army, Surgeon-General Browne, of the Navy, and Surgeon-General Wyman, of the Marine-Hospital, for their kind responses to the Secretary, and who authorized the authors to present the above papers, because they are mirrors of the present state of the rations in their respective services, and hence of great value as history. The business of this Section is simply to mirror or photograph the American dietetic knowledge of 1892.

The election of the Executive Committee on Sections was then had as follows: For three years, Dr. Kleinschmidt; for two years, Assist. Surgeon Siegfried; for one year, Dr. Hazard, of Alleghany, Pa.

The Paddock Pure Food and Drug Bill, was then brought up. The Secretary said that his interest in the bill came because for years these foods had been studied, and that in spite of all efforts fraudulent foods were made, sold and endorsed, and would continue to be, but for such a law. To be particular he instanced as a type of this class the Imperial Granum which the Conn. Agricultural Experiment Station had examined and found to be common flour, thus confirming the statement of the writer in 1882. This class fight the Paddock Bill. On the other hand such companies as the Squibb and the Doliber Goodale, for example, types of manufacturing pure preparations, welcomed the Bill and wanted it passed.

The following was then unanimously passed:

The Section of Physiology and Dietetics of the American Medical Association 1892, having duly discussed and considered The Paddock Food Bill now before Congress

Resolved, That the same is here endorsed and that they strenuously urge its passage as a most important step in the direction of the health and welfare of the Nation.

Resolved, That this action be submitted to the consideration of the American Medical Association for its endorsement.

On motion it was further

Resolved, That this Section has no objection to excepting in the Paddock Food Bill, Drugs used for industrial purposes.

Professor Herrick of Cleveland, withdrew his paper in order to read it in another Section.

The following papers were read by title and refered to the "Physiology of the Epithelia" by E. Cutter.

"Diet in its relation to the Treatment and Prevention of Diseases," by Dr. A. P. Clarke.

"Food and Hygiene of Old Age," by Dr. J. M. French.

"Medical Food Ethics, Now and to Come," by E. Cutter.

By vote the Secretary was instructed to send the resolution on the Food and Drug Bill to the Section of Materia and Pharmacy, but they had adjourned.

Ephraim Cutter, Sec'y.

Lithium Salts in the Treatment of Rheumatisms.—Practical therapeutists have for many years recognized the great value of the soluble salts of lithium, especially the carbonate and, more recently, the benzoate, in the treatment of all forms of rheumatism. Of late, however, a certain school of observers seem to have arisen abroad, who after a few laboratory experiments, which they do not describe in detail, would have us believe that all our practical experience goes for naught, and boldly declare that the idea that the lithium salts have any curative or beneficial effects in rheumatism is a superstition based on tradition, "authority" and inaccurate observations. A book has recently appeared in England (and we believe has been republished in this country), which has for its object the demolition of the "lithium salts idea." It is by a Mr. Haig, some of whose experiments are very queer to say the least. Meanwhile practical physicians will require a vast deal of theoretic biological chemistry to convince them of the worthlessness of lithium salts in gout and rheumatism. It is pleasant in this condition of things to find the following extract from a communication to *l'Union Pharmaceutique*, from so competent an observer as M. P. Adoue, pharmacist of the first class at Pauillac, in favor of lithium benzoate: M. X., who was suffering with gouty rheumatism, and had not yet tried the salts of lithium, asked me to make an analysis of his urine. I did so, and found 22 gm., 50 cgm. of urea, and 73 cgm. of uric acid to the liter. Microscopic examination revealed no hippuric acid crystals whatever. A few days later, under the advice of physicians, he commenced the use of lithium benzoate in pills, and in effervescing waters. A month later I examined his urine again, and found hippuric acid in considerable quantity; in fact, in great masses, resembling the ammonia-magnesian phosphate. The analysis showed the presence of 13 gm., 80 cgm. of urea, 95 mgm. uric acid, and 21 cgm. hippuric acid to the liter. The patient was much improved in every way and continued the use of the remedy with excellent results.—*National Druggist.*

Treatment of Ringworm.—Crawford Warren, F.R.C.S.I., in the *London Lancet*, suggests the following treatment for this troublesome affection: The affected region should first be washed with soap and warm water containing a little carbonate of soda, and then well dried. Acetic acid should then be thoroughly applied with a small brush, and on the lapse of about five minutes, when the acid will have soaked into the part, an ointment composed of sixty grains of chrysophanic acid to an ounce of lanolin should be rubbed in. This treatment should be carried out daily for such a period as may be necessary.—*Western Medical Reporter.*

Artificial Camphor.—The methods hitherto employed for the artificial production of camphor, based upon the oxidation of turpentine and analogous substances, have been found to be unprofitable on account of their cost. Nordheim claims to have discovered that the oxidizing process can be carried on at the least expense by the application of ozone or of ozonized air, for which he has obtained a patent in Germany. Chlorine gas is conducted through terebentene distilled from crude turpentine, and the resulting chlorine combination is purified from its liquid isomers in the ordinary way. It is then decomposed by an alkaline carbonate and heated to 120° C. The vaporized camphene thus produced is exposed to ozone or ozonized air to make camphor, which may be pressed in moulds, melted, or sublimed as usual.—*Druggists' Circular.*

According to Dr. H. A. Kelley, permanganate of potassium and oxalic acid are harmless to the hands and are germicidal. Soap and water plus the permanganate of potassium and oxalic acid are true germicides and the best of disinfectants

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES. . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1271, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, NOVEMBER 12, 1892.

IODIDE OF POTASSIUM IN BOVINE ACTINOMYCOSIS.

While the number of cases of human actinomycosis recorded in medical literature is still quite small, the total being in all likelihood about 300, yet it is of much interest to the scientific physician to learn of the great advances that veterinarians are making in the treatment of this otherwise intractable and fatal disease among cattle, especially because the success that has been met with would seem to warrant the expectation that the simple treatment might prove equally efficacious in human as it has done in bovine actinomycosis.

It will be remembered that actinomycosis is an infective granulomatous process depending upon the presence in the tissue of the actino-cladothrix, which consists of radiating filaments; this bacterium was formerly classed as a mould fungus and was called actinomycis, and the disease was named actinomycosis. The researches and experimental studies of AFANASSIEW and SCHULTZ, ISRAEL, BOSTROEM and MCFADYSAN have shown that the organism belongs to the highest classes of bacteria, the cladothrix, and it should be named the actino-cladothrix on account of the star-shaped arrangement of the radiating filaments. This organism has been cultivated artificially, and successfully inoculated by many investigators, among them I. and O. ISRAEL, BOSTROEM and MAX WULFF. It will be seen that much progress has been made in our knowledge of the actino-cladothrix since BALLINGER's first description of actinomycosis in cattle in 1877, and since PORFICK demonstrated the identity of human and bovine actinomycosis in 1879, although JAMES ISRAEL had described two cases of the disease in man in 1877, but without recognition of their identity with BALLINGER's disease in cattle.

The surgical treatment of human actinomycosis is, as a rule, successful when the measures employed are vigorous and thorough, removing every particle of infected granulation tissue; but in many instances the disease has progressed too far and is beyond surgical aid when the patient comes under observation, or the primary disease may be located in regions inaccessible to the surgeon for the purpose of radical removal, as in the lungs, the intestines, and the brain. HODERPYL had in 1890 found the records of thirty cases of human pulmonary actinomycosis, in nearly all of which it is safe to say that surgical measures were out of question; in eighteen of these cases the diagnosis was positively made during life by the detection of the actino-cladothrix in the sputum. Generally speaking the diagnosis of actinomycosis is easy, because the presence of sulphur-colored granules recognizable with the naked eye in the pus from acticomycotic foci will place the thoughtful physician upon his guard, and the bacteria are readily detected when the pus is examined with the microscope.

A few years ago M. THOMASSEN, of the Utrecht Veterinary School, called the attention of veterinarians to the value of the internal administration of iodide of potassium in every form of bovine actinomycosis. He pronounced it an infallible remedy. PROF. BAUG, of the Royal Veterinary College at Copenhagen, Denmark, employed the drug with the same gratifying results. Recently NOCARD, in Paris, described the disease, and cited many cases that showed conclusively that iodide of potassium radically cures actinomycotic foci in cattle that were previously deemed hopeless instances of the disease. At the instance of DR. V. NORGAARD, a Danish veterinary surgeon employed in the U. S. meat inspection Service, the Department of Agriculture at Washington is now carring on a series of experiments with iodide of potassium in bovine actinomycosis. These experiments are carried on at the Union Stock Yards in Chicago, and are watched with great interest by veterinarians, cattlemen, and farmers generally. The price of the iodide has gone up on account of the increased consumption. The same successful results appear to be as uniform and certain here as the reports of THOMASSEN, BAUG and NOCARD would lead us to expect. It will be extremely interesting to note the effects of the iodide in human actinomycosis.

And it is to be hoped that reliable men will soon have opportunity to try the drug in suitable cases. There is a possibility that the frequent secondary infection with pus microbes in actinomycotic foci in man may interfere seriously with the curative action of the potassic iodide, but a few observations would soon establish a number of facts in regard to this medicinal treatment the success of which in bovine actinomycosis appears to be so permanent that its use is certainly warranted in human forms of the disease, many of which for various reasons are not amenable to surgical treatment.

PREVENTIVE MEDICINE AND STATISTICS OF DISEASE IN VERMONT.

At the late annual meeting of the Vermont State Medical Society, the president, Dr. CAVERLY of Rutland in his address gave some very interesting facts on the above topic. Back in 1815, DR. GALLUP of Woodstock, wrote a small volume "On Epidemic Diseases in the State of Vermont." This was among the first works on infectious diseases published in this country and has both a local and historical value.

In 1857, the State began a system of gathering vital statistics, through the school district clerks, which are tabulated by the Secretary of the State. From these records some very interesting facts concerning the prevalence and mortality of diseases have been gathered. Consumption seems to lead all other diseases, and yet in a period of thirty-two years the deaths have ranged from 650 to 850 yearly. These deaths have been largely young men and women between 20 and 30 years of age, and the history of the disease in families and neighborhoods suggests a degree of infectiousness that has not been recognized. Typhoid fever has been fatal in from 100 to 550 cases a year, but has notably declined in the past few years. A knowlodge of the causes and improvement in the dwellings and drainage has made this change. As in consumption nearly sixty per cent, of the fatal cases have been young people below 30 years of age. Diphtheria has varied most widely in mortality, and is most prevalent in winter. Over two-thirds of all the deaths were under ten years of age. The eastern counties of the State have had more deaths, for the reason they were more thickly settled.

The same history of contagion is apparent here, and the fact that diphtheria is a disease particularly of the farm and country is equally clear. Numerous hints appear of the scattering of the germs by walking cases, or persons who have it so lightly as to be unsuspected, and who go about complaining of a sore throat only. The doctor makes a strong plea, to consider all doubtful cases suspicious and treat them by thorough isolation and disinfection until all possible danger is over. Diphtheria is increasing, and the doctor urges that the legislature give the health boards more power of control. That persons suffering from this malady should not be permitted to go away from home without the consent of the health authorities; that this board should have the same power as in cases of small pox, to both quarantine and disinfect all surroundings. The doctor calls attention to the preventable cases from these three diseases alone, viz.: consumption, typhoid fever and diphtheria, and remarks: "The precautions that have banished small pox from the State; that have made deaths from measles and scarlatina rare, should if well understood by the public and acted upon by the profession, greatly reduce the prevalence and mortality of typhoid, diphtheria and consumption, and hasten on the time when these diseases should be wiped out of existence."

Over two thousand deaths occur yearly by these diseases, nearly altogether of persons under 40 years of age, and this in one of the most healthful mountain States of the Union.

This address closes with an appeal to the profession to become fully acquainted with the facts of contagion and prevention, and teach the people in every neighborhood the necessity of studying and obeying sanitary laws. Along this line the highest triumphs of medicine will be attained. It is evident that such topics are inexhaustible at present, and are of exceeding interest to the profession everywhere. The statistics of such mountain States where the population is subject to but little change, and where the family physician spends a long life time in one community are far more accurate than those gathered elsewhere. Addresses and papers on these subjects have more than local interest. They are contributions that are of intense practical interest. If physicians would gather up such facts in their own neighborhoods, and point out the conditions which favor or antagonize diseases, more substantial gains would be made for science than guess work statements of the effects of remedies. The country and village physician most of all others instruct us on medical climatology and preventable medicine. for they are in a better position to do this than others. DR. CAVERLY's address should turn renewed attention to this most vital of all topics. Infectious diseases and their prevention.

RELATIONS OF PUERPERAL INSANITY TO PERVERSIONS OF OFFSPRING.

An editorial article in the *Maryland Medical Journal*, October 15, summarizes some recent publications regarding the sensational Memphis murder trial. It refers to some allegations or facts that have not hitherto been prominently mentioned. Among other statements, is one of no slight importance, to the effect that the mother of ALICE MITCHELL, the person accused of murder, was the subject of puerperal mania at the time of the birth of her eldest child, and was sent to an asylum on that account. ALICE MITCHELL's trial resulted in a verdict of unsound mind—supposed to be temporarily insane through a perverted sexual jealousy. She was committed to the Bolivar Insane Asylum. A later publication states that letters, written by the medical superintendent of that asylum, describe ALICE MITCHELL as free from all symptoms of insanity. She may, therefore, presently be released from that institution, and when that has taken place it is supposed that her arrest for murder will speedily follow.

Medically considered the point of principal interest is deemed by the writer of the article above mentioned to be is not so much the scum and filth that come to the surface when sexual perversion is the theme, but rather for the practitioner to be ready with his advice when the victims of this inherited taint or vice, as the case may be, are met with in practice. How far the parent suffering from puerperal alienation can impart to her child any tendency to perversion has not very frequently been the subject of record, but it will not be surprising if it shall be found that a certain causative relation exists. From a medical point of view, also, it is important that the profession should bear in mind that these perverts may be dangerous and violent. It is well to warn the relatives of such to be on their guard not only against sudden outbursts of passion, but also against coolly premeditated deeds of violence.

PAN-AMERICAN MEDICAL CONGRESS.

In our last issue we acknowledged the receipt of the preliminary announcement of the Congress, which forms a handsome pamphlet of 102 pages.

We note that the preliminary organization of this vast and important undertaking is commensurate with the objects in view. A satisfactory and suprising degree of forwardness is shown in the work, and there now remains the detailed preparation in the organization of the different Sections.

A series of general regulations have been adopted that shall be applicable to future Congresses, and a number of special regulations for the government of the Congress to be held next September in Washington, D. C. The registration fee has been fixed at $10 for residents of the United States. The official languages of the Congress are Spanish, French, Portugese and English. All papers are required to be printed in abstract not later that July 10, 1893, each abstract not to exceed 600 words. Papers and dissions are to be printed in the language in which they are delivered. Papers are limited to twenty minutes, longer ones are to be read in abstract, but may be printed in full in the transactions.

Dr. Reed informs us in his report that an organization to some extent has been effected in each country with the exception of Paraguay. In many instances it is complete, in others partial, but in any event it is sufficient to furnish channels through which the necessary preliminary work of the Sections may be inaugurated.

The splendid preliminary organization gives every promise of a useful and important Congress. The President of the United States has invited the constituent countries to send delegates. The American Medical Association initiated the movement leading to the organization, every member of the profession in the United States is interested in the success of the undertaking that has been so ably inaugurated.

We trust that every member of the Association will join heartily in the movement. Funds are especially needed at this time, as the expense of the preliminary organization has necessarily been considerable. It will materially aid in the work if registration fees are forwarded in advance. This may be done by a direct remittance to Dr. A. M. Owen, treasurer, Evansville, Indiana.

TUBERCULAR OSTEOMYELITIS OF THE FEMUR.

As Max Schueller has shown, there is a characteristic opposition in the manner in which the bacteria of suppuration and of tuberculosis localize and invade the tissue of a long bone. Preferably pus microbes find a footing in the medullary substance of the bone, contrasting with the so often seen tubercular epiphyseal foci. Anatomically suppuration extends throughout the shaft, as a suppurative medullitis, only at times is a bone abscess observed. Tuberculosis, in the great majority of cases, remains fixed at one or more points, forming foci of tubercular osteitis. Only in the small long bones, as in spina ventosa, does tuberculosis extend throughout the bone. The beautiful experiments of W. Mueller, although presented some time ago (1887), that were performed upon sheep and goats with a view of showing the results of injecting tubercular detritus into the *nutrient arteries* of the long bones, prove, beyond doubt, that here a diffuse tubercular inflammation is not the rule. In a series of twenty reported experiments, not once did this condition result. Still, during operations upon the large bones or upon the neighboring joints, and at times while making post-mortems in cases of miliary tuberculosis, medullary cavities are opened and accidentally found to be filled with tubercular granulations. Such a case once came to the notice of the writer. A boy, who had already recovered from an excision of a tubercular hip joint, was being operated upon for a supposed focus that remained and gave rise to the existing symptoms; as the greater trochanter was being chipped away, the osteoporosis was found to extend until at length the medulla was reached, which was full of gray granulations and detritis. Some time later the femur was canalized and finally extensive suppuration and necrosis required an amputation.

It is indeed fortunate for conservative surgery and mankind that tubercular osteomyelitis is so infrequent, as the usual end is in an amputation, or death of the patient. (Koenig). As the tuberculosis has most often advanced from an articular extremity, this, besides the medullary cavity and its walls, is also extensively diseased. Demme has described such a case, that truly deserved the name *malignant* *tubercular osteomyelitis*, as practically the entire femur was involved. In such a case, nothing but the most radical treatment can give any possibility of recovery. In the case observed the mistake was made that the entire length of the medullary cavity was not opened at once. But here, as is so often the case, the extent of the disease was not presupposed, and no preparation for so severe an operation was made. The possibility of extension to the medulla should never be overlooked, especially in operations upon tubercular joints of long standing. The delay may have caused the loss of the limb, although it is hard to place the possibility of having saved it, even had the operation been performed at once. In general, the indications and methods of treatment are closely analogous to those of suppurative medullitis and must certainly be as fully and promptly executed. As so many cases result in amputation eventually, Koenig has given primary amputation a rational position in the treatment of tubercular osteomyelitis. It should be done whenever the bone is very extensively involved, where there is tuberculosis of other large joints or when the patient is suffering from phthisis, diabetes or nephritis. Adding a final reconsideration, it must be recalled that the condition provokes but slight symptoms and on this account may quite escape notice until accidentally discovered.

HONESTY IN EXPERIMENTAL RESEARCH.

The readiness with which the results of experimental research are received by the scientific public depends largely upon the reputation and known veracity of the investigator. From some men the most remarkable announcement will at once be received without question, the acceptation of their statements being based upon the previously formed opinion of other workers, who, having repeated former experiments, find them to be correct. Upon the other hand results from certain other investigators would immediately receive criticism. The spirit of dishonesty may make itself felt in two ways, upon the side of experiment, and upon the side of the result obtained. There are those who propose certain problems to themselves, proceed to arrange experiments and then make them conform to the end they have in view. Sometimes this proof may be correct, but again, upon approaching the subject from another direction, very apparent differences may be shown. Results evidence dishonesty when they do not conform to the experiments, or are willfully misstated. This last is indeed the greater evil, because, when the data advanced are disproved, a controversy as to personal truthfulness may arise. Debate should always rule the discourse of science, and not controversy.

The cause of this occasional dishonesty may be sought for in a desire to obtain notoriety, or in a frequent wish to make gain out of failures. The honest worker is he who never hurries, accepts noth- as settled, and who does not grasp at his conclusions. Sometimes in practice a "snap" diagnosis will pass without comment, but a statement without deduction in experimentation is truly degrading. It is better to conduct experiments without object and let the results develop, and then balance each synthetically, than to make end meet end, and the amount of work conform to the ambition.

EDITORIAL NOTES.

"Dr." Conan Doyle, the Modern Scott.—The author of "The White Company," a late work of laborious historic fiction, was for eight years a medical practitioner. He possessed a degree of the University of Edinburgh, and for a time held the post of a steamship surgeon. His varied experiences in both frigid and torrid zones have without doubt served as seed-thoughts to his fertile imagination when composing those character studies or stories that are now so much sought after by the fiction-reading public. Conan Doyle has long since ceased to sport his medical title, and has only once or twice referred to his early struggles with the healing art. His books have so marked a historic tendency that they are read by students, at least, with the same kind of interest that was awakened by Sir Walter Scott. He says of himself that he devoted two years to study of the times of Edward III in order to reconstruct the band of English archers which marched unchecked through France, Scotland and Spain. These are the heroes of his "White Company."

Death of a Physician by Cholera.—Dr. K. T. Thomas, a native medical missionary, for many years located at Srinagar in Kashmir, died by cholera and overwork in July last. He was an assistant of the brothers Drs. Neve, well known in this country, who conduct two missionary hospitals on the lofty table-lands of mid-Asia. Dr. Thomas had quite exhausted himself in helping Dr. Neve in attending to cholera patients, so that when he himself was taken sick he could not rally. His loss has already been felt to be a severe one.

When the cholera swept down on Kashmir there were just two physicians—Dr. Arthur Neve and the late Dr. Thomas, Dr. Ernest Neve having gone northward into Western Thibet with Dr. Jones, a newly appointed medical missionary for the Moravian frontier station at Leh—who were available to cope with the epidemic at Srinagar. These two physicians divided the town between them for medical duty—all the other Europeans fleeing to uninfected localities. The city itself "imbedded in the filth of ages," as Dr. Neve expresses it, and the prejudices of the people fostering the spread of the disease, suffered terribly. The deaths rapidly increased from five to ten in a day to 100, then 200, then 300, and a large proportion of these were buried within the twenty-four hours in which they were taken sick.

Dr. Thomas survived these heroic labors long enough to see the mortality fall about one-half, when he became the subject of an insidious attack, being sick about four days. A transfusion seemed to prolong life a day or more, but he became unconscious towards the last, and life flickered out like a lamp that had spent its oil.

Professor Billroth's Clinic.—A handsome engraving issued by Messrs. William Wood & Co., of New York. The picture is designed for framing and a place in a physician's office, for which it is well adapted. Those desiring copies should address the publishers.

The U. S. Pharmacopœia, 1890, which will be published during 1893, adopts in great measure the *metric system* of weights and measures. In order to provide a guide to the proper dosage, etc., Dr. Geo. M. Gould, author of "The New Medical Dictionary" has prepared a table of the official and unofficial drugs, with doses in both the *metric* and *English* systems; this table is to be published in P. Blakiston, Son & Co's., Physicians' Visiting List, for 1893, together with a short description of the metric system.

SELECTIONS.

Purification of Water by Metallic Iron.—The water of Grande-Nethe, at Antwerp, has been purified during the past six years, by means of Anderson's process, which is described as follows (*Chem. Zeit.*): The water passes, with moderate rapidity, through long cylinders which are kept in rotary motion and filled with iron filings. An abundant supply of air is carried into the cylinders by a series of pipes with which they are connected. The iron, whose surfaces are constantly renewed by the motion of the cylinders, is partially changed through the action of the water into ferrous carbonate; the air decomposes the latter into carbonic acid and ferrous hydrate which is again transformed into ferric hydrate. At the same time the organic substances are consumed, or withdrawn along with the ferric hydrate deposit, which is easily collected by a filter of sand. In this way the water has been shown by analysis to be so far purified of its micro-örganisms that it may be regarded as almost sterilized. The water of the Mississippi, which holds in suspension a very large amount of foreign matter, and does not clarify by standing, parts with seven-eights of its organic substances when treated as above, and becomes almost limpid.—*Druggists' Circular.*

Craniectomy.—Bourneville (*Semaine Medical*, August 10, 1892) at the Congress of Mental Medicine, presented a number of skulls of idiots, which showed no trace of synostosis or of premature ossification. Several skulls were shown on which craniectomy had been performed, and in these and in others the sutures had not united. He goes on to prove that Lannelongue's theory of microcephalus, on which the operation of craniectomy was based, rests on an unsound basis both anatomically and physiologically, and the proceedure should, therefore, be abandoned. The author reports never having seen a single case of complete synostosis in an idiot or "backward" child. Rejis also reported a dozen cases with no benefit to the little patients. Death occurred in one case. Much stress is laid on hygienic and educational measures in treating the cases.

BOOK REVIEWS.

Psycho-Therapeutics, or Treatment by Hypnotism and Suggestion. By C. Lloyd Tuckey, M.D. Third edition. Revised and Enlarged. London: Baillière, Tindall & Cox.

In the preface to this, the third edition of his work, the author says that the increased size of the present volume is due to the wish many persons have expressed for a book dealing more fully with the theory of psycho-therapeutics. It is exactly here that we fear the reader will be disappointed, and through no fault of the writer, as he has labored diligently in gathering material from the by no means barren literature. He has succeeded admirably in presenting his results in terse readable English. Notwithstanding all the labor that has been given to the elucidation of these phenomena the fact remains that such terms as the physiology and psychology of hypnotism, hypnotic suggestion, and therapeutic suggestion are as etherial as the alleged phenomena of spiritualism and just about as hard to define.

At the time the lamented Dr. Beard visited England and exhibited some hypnotic phenomena, the profession were almost a unit in denying the facts in toto. Since that time the doubters have become less until now scarcely one can be found who denies the hypnotic state and the more or less constant phenomena connected therewith. Whether these can be correlated and capable of therapeutic application remains to be seen; certain it is that "treatment by suggestion" has a sufficient number of followers of undoubted scientific reputation to entitle it to consideration.

In the small work before us we have an excellent *résumé* of the subject up to date. While the writer is evidently a believer in the main phenomena of hypnotism, and in the practicability of the treatment of disease by this means, we notice a marked absence of special pleading that has been only too common in the more recent German and French writers on this subject.

The work is divided into ten chapters, the first eight of which are devoted to a general consideration of the subject, largely from the historical standpoint. An effort is made in these chapters to correlate many isolated facts with the phenomena of hypnotism. Examples of the power of the mind over the body are given in the first two chapters, with some explanation of the mystic and shrine cures. Then follows a description of the treatment employed by Dr. Liébault, of Nancy. It is evident that our author leans strongly to the theories advanced by the Nancy school, and for the most part rejects those of Charcot and his pupils. Then we have an account of the best methods of inducing hypnotism, together with simulation tests, a discussion of the theories of Brown-Séquard and Lauder Brunton, and of the natural analogies of hypnotism.

The last two chapters are given up to an account of cases; the first taken from the writings of others and the last from his own practice. It is apparent that treatment by suggestion must stand or fall by the results achieved in practice. Not being founded as yet on anatomical or physiological data, its sole *raison d'être* must be found in the empirical results of those who practice it.

Among the cases are the following: Insomnia of three years' standing cured. Neurasthenia improved. Five cases of occupation neuroses have been treated by the writer, one of whom was not susceptible to hypnotism, the other four improved rapidly and were cured. One case of tabes was improved temporarily and the progress of the disease seemed to be stayed. A case of torticollis cured by one treatment. The following were improved or cured: Chronic diarrhœa, paroxysmal sneezing, chronic constipation, supra-orbital neuralgia, spinal irritation, functional heart trouble enuresis, gouty sciatica, chronic rheumatism, nervous dyspepsia, amenorrhœa, dysmenorrhœa, onanism, dipsomania tobacco habit, chronic alcoholism.

Two cases seem to be especially worthy of note, one was a case of initial disease with anasarca. Suggestion improved the heart action, and the dropsy was entirely removed later by strophanthus; another was a case of extreme anæmia, in which a month's use of Blaud's pills had proved ineffectual.

We note five or six cases of failure, some of which seemed to present every hope for success. That hypnotism has been advanced as a cure-all, and that it has wholly failed in these pretensions is true, but this has been true of almost all remedies. We think that a careful reading of Dr. Tuckey's book will show that it has a certain, though limited range of applications, comparable in many respects to that of massage, Swedish movement, rest-cure, etc. As such it may prove to be a valuable adjunct in the treatment of many conditions not readily controlled by medicaments.

LEONARD'S PHYSICIANS' POCKET DAY-BOOK. Bound in Red Morocco, with Flap, Pocket, Pencil Loop and Red Edges. Price, postpaid, $1.00. Published by the *Illustrated Medical Journal* Co., Detroit, Mich.

This popular day-book is now in its fifteenth year of publication. It is good for *thirteen months*, from the first of any month that it may be begun, and accommodates daily charges for fifty patients. besides having cash department. It is bound in flexible covers, *and weighs but five ounces*, so that it is easily carried in the pocket.

ASHEVILLE, OR THE SKY-LAND. By MRS. HARRIET A. SAWYER. St. Louis. 1892. Price seventy-five cents.

This is a handsomely arranged and printed souvenir of this much written about and talked of part of our Wonderland.

MEMORANDUM ON POISONS. By THOMAS HAWKES TANNER, M.D., F.L.S. Seventh American from last London edition. Revised by JNO. J. REESE, M.D., late Professor of Medical Jurisprudence and Toxicology in the University of Pennsylvania. Philadelphia: P. Blakiston, Son & Co. Price 75 cents.

The number of editions testifies very ably to the value of this little memorandum. Its arrangement is clear, concise and not voluminous. It will prove an excellent pocket manual for practitioners.

DISEASES OF THE KIDNEYS AND BLADDER. A Text-book for Students of Medicine. W. F. MCNUTT, M.D., M.R.C.S., Ed., L.R.C.P., Ed., Professor of the Principles and Practice of Medicine, University of California, etc. Philadelphia: J. B. Lippincott & Co.; Chicago: A. C. McClurg & Co. 1893. Price $2.50.

In this book, based mainly on the lectures delivered at the University of California (San Francisco), the author takes up a class of cases which have and do prove unsatisfactory in results of treatment to a great number of physicians, owing chiefly to the length of time required for success. Dr. McNutt deals thoroughly and fairly with his subject, and his book will be found of great benefit to young practitioners as well as to students.

THE MASTOID OPERATION, INCLUDING ITS HISTORY, ANATOMY, AND PATHOLOGY. By SAMUEL ELLSWORTH ALLEN, M.D. Cincinnati: Robert Clark & Co. 1892. Price $1.25.

While containing "nothing new," as the author himself states, the above publication handles the subject matter in a clear, concise and exhaustive style that recommends it highly. The first chapter, dealing with the history of the operation, is especially interesting as giving line of work and results obtained by the first operators in this field, while the following chapters on the anatomy and pathology of the parts as well as the mode of operating, deal ably with the subject in all its aspects. The subject matter is one of serious interest not only to the surgeon, but to the general practitioner.

HISTOLOGY, PATHOLOGY AND BACTERIOLOGY. A Manual for Students and Practitioners. By BENNETT S. BEACH, M.D., Lecturer on Histology, Pathology and Bacteriology, New York Polyclinic. Student's Quiz Series. BERN B. GALLAUDET, Editor. Philadelphia: Lea Bros. & Co. Price $1.00.

A thorough understanding of the three branches here considered forms a scientific basis for a study of disease that is better appreciated every year. Students will find here a key to unlimited knowledge.

A TEXT-BOOK OF NERVOUS AND MENTAL DISEASES. By LANDON CARTER GRAY, M.D., Professor of Diseases of the Mind and Nervous System in the New York Polyclinic. Octavo, about 800 pages, richly illustrated. Lea Brothers & Co., Publishers, Philadelphia. Will be issued shortly.

ANÆSTHETICS. THEIR USES AND ADMINISTRATION. By DUDLEY WILMOT BUXTON, M.D., B.S., Member of the Royal College of Physicians; Administrator of Anæsthetics and Lecturer in University College Hospital, etc. Second Edition. Philadelphia: P. Blakiston, Son & Co. Price 50 cts.

The subject matter of this publication is one of great interest to the general practitioner as well as the surgeon. The importance of a special training for those intending to administer anæsthetics is well set forth, and physicians as well as students will find great help from a thorough study of its pages.

THE EXTRA PHARMACOPŒIA. By WM. MARTINDALE, F.C.S., Late Examiner of the Pharmaceutical Society and Late Teacher of Pharmacy at University College. Seventh edit.

The rapid strides made in the field of chemistry necessitate a like advance in all works on pharmacy. "The Extra Pharmacopœia" aims to keep abreast of the steady progress of chemistry and the newer drugs are treated of mainly, as well as any alteration in the older preparations.

GYNECOLOGY. A Manual tor Students and Practitioners. By G. W. BRATENAHL, M.D., Assistant in Gynecology, Vanderbilt Clinic, New York; and SINCLAIR TOUSEY, M.D., Assistant Surgeon, Out-patient Department, Roosevelt Hospital, New York. BERN B. GALLAUDET, M.D., Editor, Demonstrator of Anatomy, College of Physicians and Surgeons, New York. Philadelphia: Lea Bros. & Co. Price $1.00.

The value of "The Student's Quiz Series," of which the above is one, has been well proven by the steadily increasing demand for the same. This little compend will give the student a grasp of the subject that will help him greatly when pursuing a more extended course of study.

MISCELLANY.

AT THE second annual meeting of the American Electro-Therapeutic Association, held in New York, October 4, 5 and 6, the following officers were elected for the ensuing year: President—Dr. Augustin H. Goelet, of New York; Vice-Presidents—Dr. William F. Hutchinson, of Providence, R. I.; Dr. W. J. Herdman, of Ann Arbor, Mich.; Secretary—Dr. M. A. Cleaves, of New York; Treasurer—Dr. R. J. Nunn, of Savannah, Ga. Executive Committee—Dr. W. J. Morton, of New York; Dr. G. Betton Massey, of Philadelphia; Dr. Robert Newman, of New York; Dr. Chas. R. Dickson, of Toronto, Canada; Dr. J. H. Kellogg, of Battle Creek, Mich. The next meeting is to be held September 12, 13 and 14, 1893.

WANTED.—Will pay 10 cents per copy for the following numbers of THE JOURNAL: Vol. 2, No. 4, Jan. 26; No. 19, May 2, 1884. Vol. 5, No. 2, July 11; No. 3, July 18, 1885. Vol. 6, No. 6, Feb. 6, 1886. Vol. 15, No. 1, July 5; No. 4, July 26; No. 5, Aug. 2; No. 11, Sept. 13; No. 13, Sept. 27, 1890. Vol. 16, No. 1, Jan. 10; No. 2, Jan. 17; No. 3, Jan. 24, 1891. Vol. 17, No. 3, July 18, 1891.

OFFICIAL LIST OF CHANGES in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from October 29, 1892, to November 4, 1892.

Capt. Henry P. Birmingham, Asst. Surgeon U. S. A., leave of absence granted is hereby extended one month.

First Lieut Harlan E. McVay, Asst. Surgeon U. S. A., will proceed from Ft. Wingate, N. M., to the camp south of Bisbee, A. T., and report to Lieut.-Col. J. W. Barlow, corps of engineers, Commissioner of International Boundary line survey, for duty, relieving Capt. E. A. Mearns, Asst. Surgeon U. S. A.

PROMOTION.

First Lieut. Nathan S. Jarvis, Asst. Surgeon U. S. A., to be Asst. Surgeon, with rank of Captain, October 14, 1892, after five years' service, in accordance with Act of June 23, 1874.

The Journal of the
American Medical Association

Vol. XIX. CHICAGO, NOVEMBER 19, 1892. No. 21.

ORIGINAL ARTICLES.

FOOD AND HYGIENE OF OLD AGE.

Read by Title in the Section of Physiology and Dietetics, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June 7, 1892.

BY J. M. FRENCH, M.D.,
OF MILFORD, MASS.

Old age is a period of diminished energy. This is its primary, central characteristic, and carries with it a diminution of all the powers of manhood. The machinery of life is wearing out. The old man's activity is less, his paces are slower and his pulse less vigorous than when he was in his prime, his grip is less strong and his way less forceful. He no longer attempts great enterprises, nor could he carry them out if undertaken. He does not readily adapt himself to changes in his environment. His food is more slowly digested and less perfectly eliminated. His bones have become brittle, and when broken unite but slowly and imperfectly. He does not rally readily from even slight attacks of sickness, and finds himself losing each year something of the strength and elasticity of manhood. His teeth are decayed, his cheeks are sunken and his brow is wrinkled, his arteries are hardened and his hair has turned white or is fallen out. His sight is dim, his hearing dull, and all his senses have lost their acuteness; while his memory of recent events is well nigh gone, and all his mental faculties are growing weaker day by day.

The period at which this condition approaches is determined less by the number of years through which a man has passed than by his constitution and habits of life. Some men are far advanced in senility at fifty, while others seem hardly to have entered within its borders at eighty.

The man who has reached that period of advanced life which borders upon old age in reasonable health, has left many dangers behind him, and is safe from many causes of death which have menaced him along the way. The susceptibility to contagious and zymotic diseases which characterized his early life has been exhausted, and with it one great source of danger is gone. The period of manhood, which is marked by the greatest development of hereditary and general diseases, has also passed, and from it he has come forth with a constitution hardened by the storms and trials of three-score years. But now is at hand the season of old age, when local diseases manifest their greatest comparative activity and virulence. It is the weakest which now give way, and these are the three vital organs, the lungs, brain, and the heart, in the order named, and after these the stomach, liver and kidneys. Of single diseases, pneumonia carries off more aged people than any other.

There remains a considerable proportion—probably from one-third to one half—of those who reach the age of sixty-five, who, by reason of inherited endurance and favorable circumstances, survive the accidents of life, and are carried off at last by old age, that gradual fading away of the vital forces which is the only natural death.

To enable the old man to reach this end at last in safety, but not to reach it until it has been postponed to the very latest practicable moment; to adapt his environment meanwhile to his changed conditions; to conserve his strength and favor his weaknesses; and thus to conduct him safely through the dangers incident to advancing years, and bring him to the close of life by as easy a road as possible, with the greatest amount of comfort and the least of suffering—these are the objects of the hygiene of old age.

The first necessity of age as of youth is food; but errors in diet are specially harmful now. The young man has a reserve fund of vitality to draw upon, and though he may suffer acutely for a time, when too much food is taken, or food of an improper character or not properly prepared, yet he soon throws it off, and does not seem to suffer permanently. But the old man's bank account is already overdrawn, and he is living from hand to mouth. The gluttonous debauch which in early life might only have caused him a day's discomfort from indigestion, or of misery from a bilious attack, would now be liable to result in sudden death. He must therefore carefully measure his digestive power, and adapt his food, both in quantity and kind, to the needs of his system.

The old man no longer needs food to promote the growth of tissue, for tissue-growth in him has long since ceased. In his present condition of diminished activity, the waste of his tissues is also greatly lessened, and the need of food to repair this waste is correspondingly less. To maintain the vital heat is still his urgent need, and with increasing years the task grows more and more difficult.

As a whole, then, it is evident that he now requires less food than in youth or middle life, and food of a somewhat different character. Flesh food, and especially lean meat, which is chiefly useful in promoting the growth and repairing the waste of tissue, should not form a large part of the old man's diet. And observe how perfectly nature has adapted his capabilities to his needs. The teeth, which are required most of all in tearing and grinding the fibre of meat, to fit it for digestion, have now disappeared entirely, or become so weak and decayed as to be unfit for performing this office. And it is a significant fact, that in healthy individuals, whose digestive organs have not been ruined by the over-much artificiality of civilized life, the decay of the teeth is coincident with the approach of old age. As the active period of life has passed, and the food which fosters activity is no longer needed, so the means of preparing such food is no longer furnished.

Since the digestive force is now less, the food must be of such a character as to require less effort to fit it for assimilation. As the teeth can no longer grind and tear the food, it must therefore be furnished in such a form as to be early acted upon by the digestive fluids. The tendency to sluggish action of the bowels which is common in old age, requires that the nourishment should not be taken in too concentrated form, but should be of sufficient bulk, should contain enough waste matter, and be of such a character as to stimulate digestion. Of such a nature are the simpler preparations of the common cereals, as wheat, rice, oat-meal, and indian-corn; also most ripe fruits and fresh vegetables. Light mixed animal and vegetable soups are often wholesome, as is also an occasional dish of fresh fish. Nor need eggs, or even flesh food, be entirely forbidden, but only taken in great moderation. As a drink, pure water is the best, and may be taken freely. For those who, from lifelong habit, prefer warm drinks instead of cold, weak tea and coffee may be allowed. Milk may be taken as a food, provided it "ageees with the stomach," but it can hardly be considered as a drink.

Again, since large quantities of food burden the stomach and oppress the system, it is better, in old age as in infancy—in man's second childhood as in his first—that he should take food not only in much smaller quantities than in middle life, but also at more frequent intervals—say four meals a day instead of three.

All this is no new doctrine, but one that is justified by experience. Luigo Carnaro, who died at Padua, in the sixteenth century, "without any agony, sitting in an elbow-chair, being above an hundred years old," wrote several essays when between eighty-three and ninety-five years of age, in which he advocated a decreasing quantity of food at lessened intervals for the aged, to correspond with their increasing age and diminished activity.

"There are old lovers of feeding," he writes, "who say that it is necessary they should eat and drink a great deal, to keep up their natural heat, which is constantly diminishing as they advance in years; and that it is, therefore, their duty to eat heartily, and of such things as please the palate, be they hot, cold, or temperate; and that, were they to lead a sober life, it would be a short one. To this I answer, that our kind mother, nature, in order that old men may live still to a greater age, has contrived matters so that they should be able to subsist on little, as I do, for large quantities of food cannot be digested by old and feeble stomachs. By always eating little, the stomach, not being much burdened, need not wait long to have an appetite. It is for this reason that dry bread relishes so well with me; and I know it from experience and can with truth affirm, I find such sweetness in it, that I should be afraid of sinning against temperance, were it not for my being convinced of the absolute necessity of eating it, and that we cannot make use of a more natural food. And thou, kind parent nature, who actest so lovingly by thy aged offspring in order to prolong his days, hast contrived matters so in his favor, that he can live upon very little; and in order to add to the favor, and do him still greater service, hast made him sensible that, as in his youth he used to eat twice a day, when he arrives at old age, he ought to divide that food, of which he was accustomed before to make but two meals, into four, because, thus divided, it will be more easily digested; —provided, however, he lessens the quantity as his years increase. And this is what I do, agreeably to my own experience; and therefore my spirits, not being oppressed by much food, but barely kept up, are always brisk, especially after eating, so that I am obliged then to sing a song, and afterwards to write. Nor do I ever find myself the worse for writing immediately after meals, nor is my understanding ever clearer, nor am I apt to be drowsy, the food I take being in too small a quantity to send up any fumes to the brain. Oh, how advantageous it is to an old man to eat but little! Accordingly I who know it, eat but just enough to keep body and soul together."

Such a regimen as this which was advocated by Cornaro does not, of course, tend to corpulence; and indeed, old age has few greater enemies than corpulence. Heart, lungs and brain, stomach, liver and kidneys, are all oppressed thereby. Apoplexy and Bright's disease carry off the heavy-weight, while the lean and slender man, who has escaped the dangers of the middle period of life, outlives him by many years. Indeed, in looking over the octogenarians of my own acquaintance, I have been impressed by the fact that there was not one among them who could by any possibility be called corpulent, but every one was thin and spare. Surely this is a significant fact. (The Secretary confirms this.)

With reference to the use of alcoholic stimulants in old age, what shall I say? It has long been taught, and generally believed until of late, that in old age there is an especial indication for the use of spirituous liquors. But this doctrine is closely allied to that which teaches the need of large quantities of concentrated nutriment "to keep up the strength" of the aged, and the two must stand or fall together. If the principles I have been advocating are correct, then old age is the period of all others when the use of alcohol is injurious, dangerous, suicidal. With advancing knowledge, there is no longer any justification for the supposition that alcohol fosters vital heat or imparts vital force; for science has demonstrated that the sensations which seem to indicate this in either case are opposed to the fact; that alcohol lowers the temperature, lessens the powers of resistance, and at the bottom is not a stimulant at all, but rather a paralyzant. In its primary action, in moderate doses, alcohol greatly increases the work of the heart—but one of the chief dangers of old age arises from over-action of the heart; it dilates the arterioles and increases the blood supply to the brain and peripheries—but in old age all the arteries are suffering from fatty degeneration or sclerosis, and rupture easily, resulting in apoplexy, paralysis, death; it is a whip, which incites the jaded system to intenser effort—but the safety, the very existence, of old age, demands that no intense or unusual effort be required of it; it is a draft payable at sight, which enables a man to draw for to-day's needs upon the bank of to-morrow—*but old age has no to-morrow.*

It may be laid down as a general principle, that those substances whose chief action upon the nutritive system is to retard the normal rate of tissue change, while they may be valuable therapeutic remedies in conditions of disease, or even highly useful in occasional emergencies in health, cannot be considered, so far at least as this action is concerned, as proper physiological foods for daily use: for, by preventing the excretion of worn-out cells, and thereby favoring the accumulation in the system of waste products, they promote the atheromatous or fatty degeneration of healthy tissues, whether nervous, muscular, secretory or connective. As these degenerative changes throughout the whole organism are those which chiefly characterize senility, it may be said without exaggeration that whatever tends to retard tissue change, hastens the approach of old age. This is true of a large class of substances, sometimes known as accessory foods, of which alcohol, opium and tobacco are representatives. While the same property is also found to a certain extent in tea, coffee, chocolate and other articles of this class, it is in them overshadowed by other and more important ones, so that the question of the advisability or otherwise of their use cannot be decided upon this one fact alone.

Statistics show that only a small number of the habitual users of alcohol reach the age of 80 years, compared with the number of total abstainers from, or exceedingly moderate indulgers in, its use. On the other hand, so large a proportion of old men are tobacco-users in some form, as to render it somewhat questionable whether tobacco can be considered as shortening life. As to tea and coffee, it is very rare to find an abstainer among men and women of advanced life.

Rev. Peter Kimball, of Perth Amboy, N. J., will be 100 years old if he lives to March 3, 1892. He has not used rum since 1810, nor tea nor coffee since 1830. He thinks his longevity due to these abstinences mainly. March 23, 1892, he wrote me a beautiful autograph letter with thoughts, style, expression and chirography of remarkable excellence. —(Note by Secretary, March 21, 1892.)

In this connection it may be well to refer to the need of special attention to the excretory organs on the part of the aged. Regular action of the bowels and frequent evacuation of the bladder should be scrupulously maintained. The term "regular action," however, signifies quite a different thing in one person from what it does in another. While it is generally understood that one movement a day is normal, it is nevertheless true that in some persons three or more movements daily are habitual and needful for comfort, while others can go two, three or more days without discomfort and apparently without injury. But whatever the normal standard for the individual may be, once ascertained, it should be maintained with zealous care as a hygienic, I had almost said a religious duty. Chronic constipation is the deadly foe of clear-headednesss and bodily vigor, and the fruitful source of unnumbered evils, especially in women. It should be avoided as far as possible, by dietetic measures, by the force of habit, and if necessary, by medical treatment.

Of scarcely less importance is a careful attention to the kidneys and bladder. It should be an inviolable rule with the aged to attend to the calls of nature in this direction at the first indication, whatever else may wait. Enlarged prostate is a common disease in men past 65, and one which requires careful management. When aggravated by "taking cold," by the jar produced by riding over rough roads or taking long journeys in the cars, or by the irritation of a distended bladder from lack of attention to the indications of nature, obstinate retention of urine is often the result, necessitating the frequent use of a catheter, or sometimes of a trocar or aspirator, and not infrequently hastening or even directly resulting in death.

I have spoken of old age as a period of diminished activity. But I desire it to be distinctly understood that I do not mean that it is or should be a period of inactivity, but only to emphasize the change from the more intense and wider activity of manhood. For no fact is better established than the need of abundant exercise, both physical and mental, to the prolongation of life, health and vigor. Few things are more disastrous to these ends, than for a man in advanced years, accustomed to a stirring and active life, abruptly to "retire from business," thereby exchanging habits of labor for those of ease, of care for freedom, under the mistaken notion of thereby enjoying a well-earned rest for the remainder of his days. Rather should his relinquishment of business be gradual, with his lessening duties adapted to the failing energies of body and mind, but always sufficient to preserve his interest in life, and incite him to a reasonable degree of exertion. Not only is it "better to wear out than to rust out," but it takes longer to do it. If his business is such as to keep him much of the time out of doors, so much the better for his health. If not, then he needs some additional incentive to lead him into the pure air and sunshine, essential to age as to youth.

His power of resisting external influences, which in youth was strong, is now almost gone. He needs, therefore, to use special care to protect himself from heat, cold and atmospheric vicissitudes, for these are responsible for a very large proportion of what may be called the premature or accidental deaths among the aged. Especially is cold a mortal foe to old age. According to the English Registrar-General, a sudden decline of temperature results in a mortality based upon a given rule in regard to age. In persons under 30, the effect of cold is not indicated by an increase of mortality: above that age it doubles with every nine years of life. That is, for every one person at the age of 30 whose death is caused by a certain low temperature, there will be two at 39, four at 48, eight at 57, sixteen at 66, thirty-two at 75, and sixty-four at 84.

Add to the effects of cold those of heat, moisture, winds and sudden changes of temperature, and we have, in a climate like ours, a most formidable array of dangers to old age from atmospheric causes. To guard against these, the old man must not only suit his food to the climate and season, but he must clothe himself warmly—preferably in woolen garments, as being the poorest conductor of heat—must avoid all undue exposure either to extreme or sudden changes of temperature, and must occupy a comfortable room. His sleeping-rooms should be warm, well-aired and dry. Many a time has the "spare room" proven fatal to gray hairs and decrepit age, resulting in "a cold," pneumonia, death.

Statistics show that more women than men become old. In Massachusetts, out of 203 persons dying at the age of 100 or more, from 1880 to 1890, 153 were females, and only fifty-two males. It may reasonably be supposed that a part of the superior longevity of woman is due to her more quiet, regular and temperate life, less injury from passion and excitement, and less exposure to atmospheric vicissitudes. If this be the case, it furnishes a valuable means of preparing such food is no longer furnished.

Since the digestive force is now less, the food must be of such a character as to require less effort to fit it for assimilation. As the teeth can no longer grind and tear the food, it must therefore be furnished in such a form as to be early acted upon by the digestive fluids. The tendency to sluggish action of the bowels which is common in old age, requires that the nourishment should not be taken in too concentrated form, but should be of sufficient bulk, should contain enough waste matter, and be of such a character as to stimulate digestion. Of such a nature are the simpler preparations of the common cereals, as wheat, rice, oat-meal, and indian-corn; also most ripe fruits and fresh vegetables. Light mixed animal and vegetable soups are often wholesome, as is also an occasional dish of fresh fish. Nor need eggs, or even flesh food, be entirely forbidden, but only taken in great moderation. As a drink, pure water is the best, and may be taken freely. For those who, from lifelong habit, prefer warm drinks instead of cold, weak tea and coffee may be allowed. Milk may be taken as a food, provided it "ageees with the stomach," but it can hardly be considered as a drink.

Again, since large quantities of food burden the stomach and oppress the system, it is better, in old age as in infancy—in man's second childhood as in his first—that he should take food not only in much smaller quantities than in middle life, but also at more frequent intervals—say four meals a day instead of three.

All this is no new doctrine, but one that is justified by experience. Luigo Carnaro, who died at Padua, in the sixteenth century, "without any agony, sitting in an elbow-chair, being above an hundred years old," wrote several essays when between eighty-three and ninety-five years of age, in which he advocated a decreasing quantity of food at lessened intervals for the aged, to correspond with their increasing age and diminished activity.

"There are old lovers of feeding," he writes, "who say that it is necessary they should eat and drink a great deal, to keep up their natural heat, which is constantly diminishing as they advance in years; and that it is, therefore, their duty to eat heartily, and of such things as please the palate, be they hot, cold, or temperate; and that, were they to lead a sober life, it would be a short one. Oh, how advantageous it is to an old man to eat but little! Accordingly I who know it, eat but just enough to keep body and soul together."

Such a regimen as this which was advocated by Cornaro does not, of course, tend to corpulence; and indeed, old age has few greater enemies than corpulence. Heart, lungs and brain, stomach, liver and kidneys, are all oppressed thereby. Apoplexy and Bright's disease carry off the heavy-weight, while the lean and slender man, who has escaped the dangers of the middle period of life, outlives him by many years. Indeed, in looking over the octogenarians of my own acquaintance, I have been impressed by the fact that there was not one among them who could by any possibility be called corpulent, but every one was thin and spare. Surely this is a significant fact. (The Secretary confirms this.)

With reference to the use of alcoholic stimulants in old age, what shall I say? It has long been taught, and generally believed until of late, that in old age there is an especial indication for the use of spirituous liquors. But this doctrine is closely allied to that which teaches the need of large quantities of concentrated nutriment "to keep up the strength" of the aged, and the two must stand or fall together. If the principles I have been advocating are correct, then old age is the period of all others when the use of alcohol is injurious, dangerous, suicidal. With advancing knowledge, there is no longer any justification for the supposition that alcohol fosters vital heat or imparts vital force; for science has demonstrated that the sensations which seem to indicate this in either case are opposed to the fact; that alcohol lowers the temperature, lessens the powers of resistance, and at the bottom is not a stimulant at all, but rather a paralyzant. In its primary action, in moderate doses, alcohol greatly increases the work of the heart—but one of the chief dangers of old age arises from over-action of the heart; it dilates the arterioles and increases the blood supply to the brain and peripheries—but in old age all the arteries are suffering from fatty degeneration or sclerosis, and rupture easily, resulting in apoplexy, paralysis, death; it is a whip, which incites the jaded system to intenser effort—but the safety, the very existence, of old age, demands that no intense or unusual effort be required of it; it is a draft payable at sight, which enables a man to draw for to-day's needs upon the bank of to-morrow—*but old age has no to-morrow.*

It may be laid down as a general principle, that those substances whose chief action upon the nutritive system is to retard the normal rate of tissue change, while they may be valuable therapeutic remedies in conditions of disease, or even highly useful in occasional emergencies in health, cannot be considered, so far at least as this action is concerned, as proper physiological foods for daily use: for, by preventing the excretion of worn-out cells, and thereby favoring the accumulation in the system of waste products, they promote the atheromatous or fatty degeneration of healthy tissues, whether nervous, muscular, secretory or connective. As these degenerative changes throughout the whole organism are those which chiefly characterize senility, it may be said without exaggeration that whatever tends to retard tissue change, hastens the approach of old age. This is true of a large class of substances, sometimes known as accessory foods, of which alcohol, opium and tobacco are representatives. While the same property is also found to a certain extent in tea, coffee, chocolate and other articles of this class, it is in them overshadowed by other and more important ones, so that the question of the advisability or otherwise of their use cannot be decided upon this one fact alone.

Statistics show that only a small number of the habitual users of alcohol reach the age of 80 years, compared with the number of total abstainers from, or exceedingly moderate indulgers in, its use. On the other hand, so large a proportion of old men are tobacco-users in some form, as to render it somewhat questionable whether tobacco can be considered as shortening life. As to tea and coffee, it is very rare to find an abstainer among men and women of advanced life.

Rev. Peter Kimball, of Perth Amboy, N. J., will be 100 years old if he lives to March 3, 1892. He has not used rum since 1810, nor tea nor coffee since 1830. He thinks his longevity due to these abstinences mainly. March 23, 1892, he wrote me a beautiful autograph letter with thoughts, style, expression and chirography of remarkable excellence. —(Note by Secretary, March 21, 1892.)

In this connection it may be well to refer to the need of special attention to the excretory organs on the part of the aged. Regular action of the bowels and frequent evacuation of the bladder should be scrupulously maintained. The term "regular action," however, signifies quite a different thing in one person from what it does in another. While it is generally understood that one movement a day is normal, it is nevertheless true that in some persons three or more movements daily are habitual and needful for comfort, while others can go two, three or more days without discomfort and apparently without injury. But whatever the normal standard for the individual may be, once ascertained, it should be maintained with zealous care as a hygienic, I had almost said a religious duty. Chronic constipation is the deadly foe of clear-headednesss and bodily vigor, and the fruitful source of unnumbered evils, especially in women. It should be avoided as far as possible, by dietetic measures, by the force of habit, and if necessary, by medical treatment.

Of scarcely less importance is a careful attention to the kidneys and bladder. It should be an inviolable rule with the aged to attend to the calls of nature in this direction at the first indication, whatever else may wait. Enlarged prostate is a common disease in men past 65, and one which requires careful management. When aggravated by "taking cold," by the jar produced by riding over rough roads or taking long journeys in the cars, or by the irritation of a distended bladder from lack of attention to the indications of nature, obstinate retention of urine is often the result, necessitating the frequent use of a catheter, or sometimes of a trocar or aspirator, and not infrequently hastening or even directly resulting in death.

I have spoken of old age as a period of diminished activity. But I desire it to be distinctly understood that I do not mean that it is or should be a period of inactivity, but only to emphasize the change from the more intense and wider activity of manhood. For no fact is better established than the need of abundant exercise, both physical and mental, to the prolongation of life, health and vigor. Few things are more disastrous to these ends, than for a man in advanced years, accustomed to a stirring and active life, abruptly to "retire from business," thereby exchanging habits of labor for those of ease, of care for freedom, under the mistaken notion of thereby enjoying a well-earned rest for the remainder of his days. Rather should his relinquishment of business be gradual, with his lessening duties adapted to the failing energies of body and mind, but always sufficient to preserve his interest in life, and incite him to a reasonable degree of exertion. Not only is it "better to wear out than to rust out," but it takes longer to do it. If his business is such as to keep him much of the time out of doors, so much the better for his health. If not, then he needs some additional incentive to lead him into the pure air and sunshine, essential to age as to youth.

His power of resisting external influences, which in youth was strong, is now almost gone. He needs, therefore, to use special care to protect himself from heat, cold and atmospheric vicissitudes, for these are responsible for a very large proportion of what may be called the premature or accidental deaths among the aged. Especially is cold a mortal foe to old age. According to the English Registrar-General, a sudden decline of temperature results in a mortality based upon a given rule in regard to age. In persons under 30, the effect of cold is not indicated by an increase of mortality: above that age it doubles with every nine years of life. That is, for every one person at the age of 30 whose death is caused by a certain low temperature, there will be two at 39, four at 48, eight at 57, sixteen at 66, thirty-two at 75, and sixty-four at 84.

Add to the effects of cold those of heat, moisture, winds and sudden changes of temperature, and we have, in a climate like ours, a most formidable array of dangers to old age from atmospheric causes. To guard against these, the old man must not only suit his food to the climate and season, but he must clothe himself warmly—preferably in woolen garments, as being the poorest conductor of heat—must avoid all undue exposure either to extreme or sudden changes of temperature, and must occupy a comfortable room. His sleeping-rooms should be warm, well-aired and dry. Many a time has the "spare room" proven fatal to gray hairs and decrepit age, resulting in "a cold," pneumonia, death.

Statistics show that more women than men become old. In Massachusetts, out of 203 persons dying at the age of 100 or more, from 1880 to 1890, 153 were females, and only fifty-two males. It may reasonably be supposed that a part of the superior longevity of woman is due to her more quiet, regular and temperate life, less injury from passion and excitement, and less exposure to atmospheric vicissitudes. If this be the case, it furnishes a valuable as to the kind of life which should be followed, not only by those who would grow old, but by those who, having already reached advanced life, desire still further to prolong their days.

The integrity of the heart and nervous system demands that the old man should avoid all extreme or sudden physical exertion, all intense and depressing mental emotion. Running to catch the cars, lifting a heavy weight, making an eloquent and impassioned after-dinner speech, or indulging in a paroxysm of passion—all these have often been proven to be only forms of suicide for the weakened heart and brittle arteries of the aged. The safety of gray hairs depends rather upon the regular continuance in accustomed paths, where to go on is easier than to stop or turn aside. Habits are strong in the decline of life, and not easily changed. To act in accordance with these is to travel in the line of the least resistance.

The man who has ceased to take an active concern in what is going on in the world about him, has but a feeble hold upon the world itself. When the wish and the will to live are gone, life is sure soon to go too. Dr. George M. Beard has well said that it does not take much experience in practice for a physician to learn that men die who might just as well live if they only resolved to live, and that myriads who are invalids could become strong if they had the native or acquired will to vow they would do so.

A cheerful disposition, which enables its possessor to see the bright side of everything, and prevents him from wearing himself out with worry when things do not go to suit him, is a potent factor in prolonging life. Mental activity, if not coupled with too much nervous strain, may with advantage be kept up to the close of life. It is a well-known fact that literary and scientific men are as a rule long-lived. In all countries, ministers among professional men, and farmers among manual laborers, are the longest-lived classes in the community, and they are exactly the ones who enjoy the benefits of mental and physical labor under the most favorable conditions.

Of prime importance is sleep. Sleep oils the wheels of life, and lessens the friction of labor. The want of it causes all the machinery of life to run with difficulty, and wear out rapidly. Sleep recreates the nervous system—and sleeplessness breaks down the strongest frame. Especially does old age need abundant sleep, that all the vital forces may be carefully husbanded.

To sum up briefly: The food of old age should be simple, nutritious but not too concentrated, not too largely nitrogenous. It should be taken four times a day, in less quantity as a whole than in middle life, and in a soft and friable condition. Stimulants and narcotics should be avoided, unless required by lifelong habit. Tea and coffee may be allowed in moderation. The calls of nature should be promptly attended to. All excesses should be avoided, and regularity, temperance and moderation observed in all things. Careful protection from cold and atmospheric vicissitudes is required. The mind should be kept active to the last. Avoid worry and fret. Look on the bright side of life. Take plenty of sleep. Have the best of care in health, and of nursing in sickness. Avoid passion, excitement, luxury, overexertion. Thus will life be lengthened, and old age made enjoyable.

HYPERTROPHY OF THE PHARYNGEAL TONSIL.

A clinical lecture delivered at the College of Physicians and Surgeons, Chicago, May 12, 1892.

BY O. PRESCOTT BENNETT, M.D.,
INSTRUCTOR IN LARYNGOLOGY AND RHINOLOGY, CHICAGO POLICLINIC.

Synonyms.—Hypertrophy of Luschka's tonsil. Adenoid vegetations of naso pharynx, post-nasal growths or vegetations.

Definition.—This affection may be defined as an abnormal enlargement of the lymphoid structures normally found at the vault of the pharynx, frequently causing partial deafness, alterations in the voice, more or less nasal obstruction, with occasional deterioration of the general health.

History.—Czermak[1] was probably the first to have seen these growths and as early as 1860 described them with considerable accuracy, but failed to recognize their clinical importance. Voltolini[2], in 1865, described a case of deafness associated with, and probably due to this hypertrophy. Löwenberg[3] published a similar account of three cases in the same year and made some commendable suggestions as to their pathological anatomy. Meyer,[4] of Copenhagen, in 1868, was the first to insist on their clinical importance. His interesting paper, in which he gave an admirable account of the symptoms, detailed the microscopical appearances and pointed out the mode of treatment which he had found most useful, was based on a study of one hundred and two cases.

Subsequent writers have given us little of any importance that was not thoroughly understood by Meyer, while our increased clinical experience with the disease, has also demonstrated the correctness of most of his original views.

Etiology.—For convenience the causes of this condition may be divided into the predisposing and exciting ones. Among the former may be mentioned heredity, which so far as known plays very little part in its etiology, yet the disease has been understood for so short a time that it is impossible to determine whether the parents of these patients have ever suffered from a similar condition or not. Several children of the same family are commonly found so affected.

The disease is said to be more frequently found among those of the Jewish race, than of any other. It is essentially a disease of children and young adults, being rarely found after thirty years of age. Sex appears to have no influence in its production. Cold, damp climates are said, by some, to be very productive of this disease, but this has doubtless been unduly exaggerated by a majority of writers. Anterior stenosis of some form or other is associated with a large number of these cases. This is more often caused by hypertrophy of the inferior turbinated body, but not unfrequently do we find some deviation of the septum sufficient to produce more or less obstruction of one or both nostrils. About sixty per cent. of all cases of enlarged oral tonsils suffer from post-nasal growths and nearly all patients having cleft palates have them also.

Meyer[5] attributes the latter fact to the direct irritation of the mucous membrane, produced by the food passing into the naso-pharynx, but this is a rare complaint in these cases and probably has nothing to do with its cause. Billroth[6] has pointed out that by the contraction of the upper constrictor, the pharynx is brought nearly into apposition with the margins of the hard palate, and the tonsils being approximated by the same agency, the cleft is almost closed. Löwenberg[7] believes the lymphatic temperament to be the cause in a majority of the cases which he has seen. Such a temperament according to his description would appear to be identical or allied to struma, which Meyer,[8] Mackenzie,[9] Bosworth,[10] and Browne, [11] do not consider as any etiological factor at all.

The exciting causes seem to be about the same as those causing the enlargement of the oral tonsils. The exanthematous diseases, especially measles, and scarlet-fever, and diphtheria occupy a prominent place. Frequent colds and unsanitary surroundings, especially in children liable to catarrhal trouble, may be the cause in some cases. Purulent and muco-purulent rhinitis is occasionally associated with this condition, but whether the cause or the effect, I am unable to state. Atrophic rhinitis has been observed by Bosworth [12] in four of his cases.

You will be unable to determine the date of the commencement of this trouble and its exact etiology in a great many of the patients which you will be called upon to treat.

Symptoms.—The first symptom which usually attracts the attention of the child's parents or attendants is the labored breathing or snoring during sleep. This is invariably present in a greater or less degree, but may exist only a part of the night. It is caused by the impinging of the indrawn current of air on the soft palate, which is thrust forward and downward by the growth. Not infrequently do we hear this sound when the child's mouth is entirely closed. In these cases the palate is set vibrating by the inspired air directed upon its upper surface. The breathing is usually labored and when the growth has attained considerable size, it may at times seem entirely or partially arrested. The attacks of dyspnœa may be so severe as to resemble laryngismus stridulus. Shortness of breath is frequently noticed on slight exertion.

The child is usually restless, and often wakes during the fore part of the night, occasionally with a mild delirium, but towards morning sinks into a deep sleep from which he awakes with a headache and a feeling of malaise which may last for several hours. Older patients frequently complain of a lack of ambition and a dry, bad-tasting mouth on rising in the morning, which wears off as the day advances. Mouth breathing is quite a prominent symptom, and may be present when the growth is very small. This is not so noticeable during the day when the patient is awake, but during sleep, when the voluntary muscles of respiration are not brought into play, the mouth is nearly always open.

There is frequently more or less deafness, with an occasional suppurative otitis-media. There are no complications of so great importance, or which deserve so prompt recognition as these ear troubles, for when neglected, they may result in the permanent loss of their important function. The defective hearing is claimed by many to be either the result of the pressure of the growth on the Eustachian tubes, causing their obstruction, or to the extension of the inflammation to the middle ear. The majority of middle ear troubles, however, are probably due o the stagnation and consequent rarification of the ir in the vault of the pharynx and Eustachian tubes, caused by the obstruction to the normal nasal respiration.

Speech is thick and indistinct and does not differ materially from that found in other forms of nasal obstruction. It is frequently impossible for the patient to pronounce m, and n; b, being used for the former, and d, for the latter. There is occasional complaint that the younger patients seldom blow their nose, although the voice sounds as if they had a cold in the head. In adults, as it requires a greater effort for the production of high tones, the voice usually tires very easily after singing a short time. There is nearly always a profuse post-nasal discharge of mucus or muco-pus of a thick ropy consistency, which necessitates the patients clearing the naso-pharynx by acts of hawking. Occasionally, though not often a chronic rhinorrhœa may exist.

Cough is frequently due to the continued mouth breathing or to the secretions making their way into the pharynx or larynx. A barking reflex cough is occasionally observed. Headache at times is annoying. Epistaxis is somewhat rare although the child may once in a while expectorate some mucous streaked with blood.

Chatillier,[13] mentions both night-mare and night sweats as symptoms. The latter is found in a small proportion of cases, probably due more to the impaired general health than to the local condition. Children are usually exceedingly stupid, unable to fix their attention, and have an inaptitude for intellectual work. The appetite is usually capricious and there may be some disorder of digestion. There is usually more or less impairment of olfaction and of the sense of taste.

There is no objective symptom more noticeable or characteristic, especially in children, than the peculiar facial appearance. The mouth is opened, the lower jaw hangs down and the lips are prominent, but expressionless. The bridge and root of the nose are broad and flattened; the alæ dimpled and collapsed; the cheeks seem flattened and the eye-brows depressed.

Spicer[14] has called attention to a somewhat unique symptom, which he has observed in a number of cases, namely, the presence of an enlarged transverse vein at the root of the nose. He believes this to be due to the pressure of the enlarged gland on the outlet of veins as they pass through the spheno-palatine foramina. This is occasionally observed, but it is by no means common.

On examination, the membrana tympani is usually thickened, sometimes congested, and in all cases more or less depressed. This great depression is claimed by MacDonald,[15] to be pathognomonic of this condition. It is probably due to the fact, that the oxygen contained in the air, imprisoned in the Eustachian tubes, is exchanged for carbonic acid, which, being dissolved in the mucus, somewhat lessens the intra-tympanic pressure. Atmosphere not being allowed to enter the tubes, exerts its pressure from without on the drum-head and drives it inward.

The nasal fossæ are found abnormally small in some cases. There is nearly always some hypertrophy or turgesence of the inferior turbinated bodies. The faucial tonsils are often enlarged and masses of glandular tissue can usually be seen at the side of the pharynx, back of the posterior pillars of the fauces. The edges of the soft palate are congested, rounded and flabby. The uvula is congested and œdematous. Frothy mucus or muco-purulent secretion can be seen on the posterior wall of the pharynx coming down from the pharyngeal vault. On the removal of this, the posterior wall appears more or less granular. The follicles are arranged symmetrically and become larger as they ascend, until just above the edge of the palate they blend with the glandular hypertrophy in the naso-pharynx.

If sufficient care and patience are exercised, a thorough examination of the parts can usually be made with the rhinoscope. The hypertrophy appears attached to the posterior wall and vault of the pharynx, is more or less nodular and has a well defined cushion-like appearance, (see Fig. 1). It is usually of a pale pink or grayish color. In rare instances it hangs from the vault of the pharynx as separate or pedunculated growths.

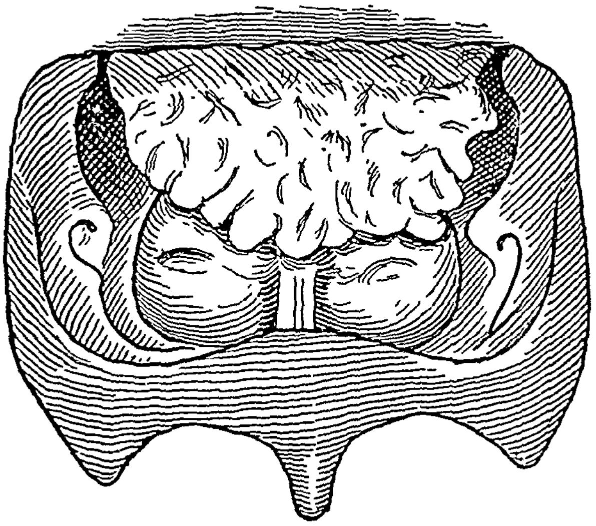


Fig. 1.—Hypertrophy of the pharyngeal tonsil.

The surface is never granular but may at times be coarsely lobulated. Blood vessels are never seen on its surface. In adults, where the growth has commenced to atrophy, it has a much smoother appearance. The enlargement interrupts the view of the broad upper part of the septum, and its size can be estimated by the extent to which this is indiscernable. (See Fig. No. 1).

In those cases in which a posterior rhinoscopic examination can not be made, as in some children, it will be necessary to make a digital exploration of the parts. In doing so a gag should be inserted between the teeth, the forefinger of the right hand carried back to the pharyngeal wall and then turned up behind the palate, where you will at once detect the glandular enlargement. Those of you who are unfamiliar with the feeling of a normal naso-pharynx will do well to follow out the suggestions of Lennox Browne[16] which are, that the finger should first feel for the lower part of the septum, when the posterior nares can be explored. The Eustachian orifice with its cartilaginous cushion can then be made out laterally. The roof can be examined by passing the finger from the septum upwards and backwards. Very slight hæmorrhage may follow this examination, but it is not especially painful to the patient.

Chronic rhinitis, pharyngitis and laryngitis will be found associated with this condition in a great many cases. An occasional deformity of the chest, known as the pyriform or pigeon breast, is said by some to result from this condition.

Pathology.—An examination with a higher power microscope proves these hypertrophies to be simply a hyperplasia of the glandular structure, normally found at the vault of the pharynx, and not of the nature of new growths. They are highly vascular and are covered with a layer of columnar ciliated epithelium. They consist of an over-growth of the lymphoid and connective tissue, nearly identical to that found in hypertrophy of the oral tonsils, and are composed of a number of lymph follicles which are inclosed and separated from each other by a retiform connective tissue.

Diagnosis.—When we consider the subjective symptoms, the facial expression, dead voice, and the result of the rhinoscopic or digital examination, the diagnosis seldom presents any difficulty. Occasionally fibrous tumors of the naso-pharynx, retro-pharyngeal abscess, mucous polypi and posterior hypertrophy of the inferior turbinated bodies have been mistaken for this affection. Fibrous tumors are very much harder, bleed easily and profusely, are usually bright red or purple in color, have enlarged blood vessels on their surface and when large, may cause distortion of the parts. Mucous polypi rarely occur at so early an age; nearly always extend from the nose into the naso-pharynx; are soft, movable and transparent, and blood vessels are frequently seen coursing across their surface. The posterior wall of the pharynx is not involved and they can nearly always be detected by anterior rhinoscopy. In posterior hypertrophy of the inferior turbinated bodies, the growth is in front and not posteriorly. Retro-pharyngeal abscess is accompanied by more or less pain, especially in swallowing and is often insidious. There is some tenderness and pitting on pressure. The enlargement usually extends far down on the posterior wall.

Bosworth[17] has recommended a very simple means of determining whether there is any obstruction to the nose and naso-pharynx, by means of a heavy oil, as liquid vaseline used in an oil atomizer, producing a spray of like density to smoke. This when sprayed into one nostril, should the cavities be free, will emerge from the opposite, in the same amount and with the same force as it went in. When there is some obstruction, the spray, if it emerges at all, will be in a very small amount and its force very much diminished. This is certainly a very easy test and is regarded by Bosworth as being a very sure one. However, I would not place too much reliance on this test alone.

Prognosis.—In about seventy-five per cent. of these cases, the glandular enlargement will atrophy, if left to itself, at about the fourteenth or fifteenth year, but in the meantime irreparable damage may be done to the hearing, voice and general health. The result of proper treatment in these cases is highly satisfactory, and when commenced early in the course of the disease the entire train of symptoms usually disappear.

When there are grave ear troubles, which have existed for some time, the prognosis must be more guarded. There is always some improvement and arrest of further extension of it, but perfect restoration of hearing can not be obtained in all cases. The natural voice is not always immediately restored.

Treatment.—As a rule medical treatment is of no value. I have occasionally derived some benefit from the use of the syrup of the iodide of iron, especially in anæmic children. It is very doubtful however, if absorption of these growths is ever promoted by the administration of an internal remedy. General tonics are frequently indicated on account of the impairment of the general health due to the imperfect oxygenation of the blood and to the disturbed rest. Cod-liver oil, when tolerated, will undoubtedly give the most satisfactory results.

Local medication is also very unsatisfactory in a majority of cases. Astringents may prove useful, by limiting the amount of the discharge, and preventing the recurrence of the frequent attacks of acute inflammation to which these patients are liable, but very little permanent benefit is derived from their use. No absolute cure can be obtained except by a thorough removal of the abnormal tissue. Tannin is probably the best astringent and should be used in solution by means of a Davidson's No. 59 atomizer, for with it you will be able to reach the parts satisfactorily, without doing any damage to the neighboring organs.

The following is the formula which I prefer.

℞. Acidi carbolici, grs. ij.
Sodii biboratis, grs. vj.
Acidi tannici, grs. xx to xl.
Glycerini, ʒiv.
Aquæ, q. s. ad. ℥ij.
M. S.—To be used as a-spray twice a day.

This forms a suitable, cleansing and astringent solution, which very often gives considerable relief to the sufferers from this condition.

In a few cases, in which I have have not been allowed to operate, I have reduced the hypertrophy quite successfully by means of chromic acid. After the application of a small amount of cocaine, by means of a spray, to the naso-pharynx and oiling the nasal cavities, the acid, which has previously been fused on the end of a flat aluminum probe is passed though the nostril to the enlarged pharyngeal tonsil, where it is held in contact for a few minutes. It usually causes a very little pain and soreness, but both disappear in a short time. The applications should be repeated about every three to five days and made alternately through the opposite nostril.

The galvano-cautery may be used for the same purpose by means of a straight electrode, passed through the nose to the naso-pharynx, or by means of a bent electrode passed up behind the palate. The great objection to these two methods of treatment, is that they require the repetition of many applications, which necessarily involves a long course of treatment. They frequently cause considerable pain, and very often the results are not nearly so satisfactory as we had anticipated.

Complete removal of the growth I believe to be the only scientific treatment and should be resorted to in preference to any other. For this purpose, any number of instruments have been invented. Lennox Browne[18] prefers the finger nail of the index finger to any instrument, believing that by energetic nail scraping, he can remove the growth more thoroughly and easily, save time and prevent injury to the Eustachian orifice. Löwenberg forceps, or some modification of them, is probably used more often than any other instrument for their removal. The modification of the forceps suggested by Dr. John N. Mackenzie, of Baltimore, has proved the most satisfactory to me.

An anæsthetic should always be used with children. Chloroform, although perhaps not quite as safe an anæsthetic as ether, is preferable for the reason that the latter stimulates the out-pouring of an inconvenient amount of saliva, produces congestion of the mucous membranes and so increases the amount of hæmorrhage. When the anæsthesia is complete, the patient should be turned on his side and face, with his mouth over the edge of the table. A suitable gag, such as Hénrotin's or Goodwille's having been inserted so as to separate the teeth, the surgeon standing on the right side of and facing the patient, passes the forefinger of the left hand behind the palate into the upper pharynx, where it is held as a guide. The forceps are then passed along the anterior surface of the finger and the growth removed piece by piece, guided each time by the finger until it has been completely taken away. Care should be taken to avoid tearing the mucous membrane and seizing the posterior edge of vomer or Eustachian cushion, which, to the uneducated finger, feel like the abnormal growth. If you carefully feel each portion of the neoplasm grasped by the forceps and avoid turning them side-ways, there is very little danger of doing any damage, provided you are familiar with the normal feeling of the parts. After having removed the greater amount of the growth, small excresences may be found hanging down behind the posterior nares. These remnants should be carefully searched for and thoroughly removed for their presence obstructs nasal respiration considerably.

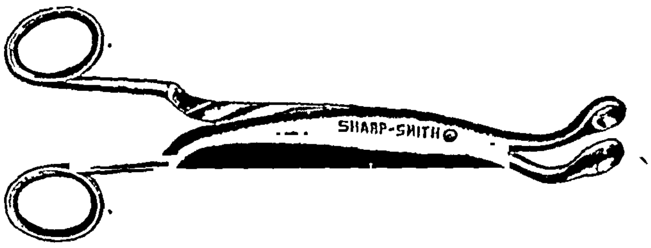

Fig. 2. Dr. Mackenzie's modification of Löwenberg's forceps.

In those cases, in which there is some difficulty in removing them by means of the instrument which I have just described, a straight nasal forceps, with cutting edges such as is used by Ingals, can be passed through the nostril to the proper point in the naso-pharynx, guided by the finger which is still retained behind the palate, and the part removed very readily.

The hæmorrhage is occasionally rather profuse, but usually ceases with the operation. With the patient in the position I have recommended, there is no necessity of swabbing or sponging out the throat as the blood can not get into the trachea, but with the patient on his back, the shoulders slightly raised and the head thrown far backward, as is recommended by some English surgeons, it is a necessity in order to prevent the blood getting into the air-passages. If undue hæmorrhage should occur, which is very rarely the case, it may become necessary to pack the posterior nares.

When the operation is completed, the mouth should be wiped out and as much blood as can, be squeezed out of the nose. It is not necessary, nor is it desirable to wash out the nose for about a week, unless there is a bad odor to the discharge, for even sprays sometimes find their way to the middle ear.

In adults, general anæsthesia is often unnecessary, it being quite sufficient to anæsthetize the parts by means of a solution of cocaine. The following is the combination which I use.

R. Atropinæ sulphatis, gr. 1-10.
Strophanthin., gr. 1-12.
Acidi carbolici, grs. v.
Olii caryophylli, gtts. v.
Cocainæ Muriatis, grs. xx.
Glycerini, ʒiv.
Aquæ q. s. ad. ℥i.

I have used this solution as a local anæsthetic for some time and find it much superior to the solutions of cocaine ordinarily used. Its advantages are the following: its strength does not deteriorate with age; it is a much stronger local anæsthetic than solutions containing the same amount of cocaine; its local effect is more lasting, while the constitutional disturbances are reduced to a minimum.

The position of the patient should be the same as that assumed for making a posterior rhinoscopy. My own custom has been to apply a small amount of the same solution by means of a spray to the naso-pharynx. A few drops can be applied to the upper part of the gland by passing a long silver canula, fastened to a hypodermic syringe, through the nose to the naso-pharynx. The applications should be repeated about once a minute until the parts are sufficiently anæsthetized. A self retaining palate retractor should be inserted and the patient may depress his own tongue by means of a tongue spatula. The forceps can be guided by the aid of the post rhinal mirror and one or two large bites taken, but after that, the blood obstructs the view and the operation will have to be completed by the sense of touch. There is frequently some pain after the two or three pieces have been removed, and the patients usually prefer to leave the remainder of the operation to a future time. In this way, it may require two or three sittings to completely remove the growth.

For the last year I have used Gottstein's new improved post-nasal curette for the removal of these vegetations, with the greatest satisfaction. It appears to me to be far superior to any other instrument used for this purpose. Chloroform or ether are unnecessary. The growth can be removed thoroughly at one sitting and usually by one stroke, when the instrument is introduced properly. Its shape is such that injury to the adjacent structures is impossible.

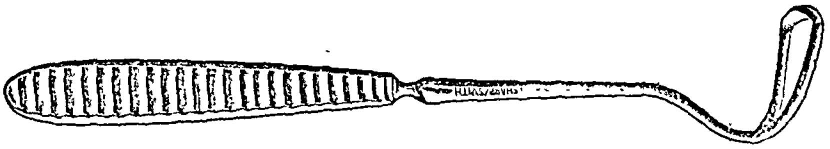

Fig. 3.—Gottstein's old naso-pharyngeal curette.

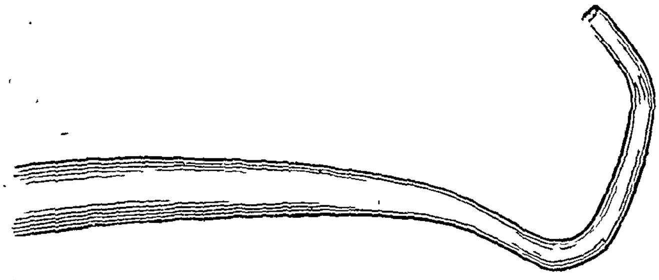

Fig. 4.—Gottstein's new naso-pharyngeal curette.

The improvement of Gottstein's new curette over the old one, is in the peculiar curvature of the cutting part of the instrument, it being especially adapted to the anatomy of the pharyngeal vault, so that the removal of any part of the pharynx other than the hypertrophy is made impossible.

An anæsthetic is not absolutely necessary, but I should always recommend the giving of nitrous oxide when it is possible, especially to children, for their memory of pain is lasting.

The child is placed upright in a surgical chair with a basin in its lap. The hands should be held by an assistant. Nitrous oxide having been administered, the curette is introduced into the mouth sideways, passed beneath the soft palate and carried up along the anterior wall of the naso-pharyngeal space until the vault is reached.

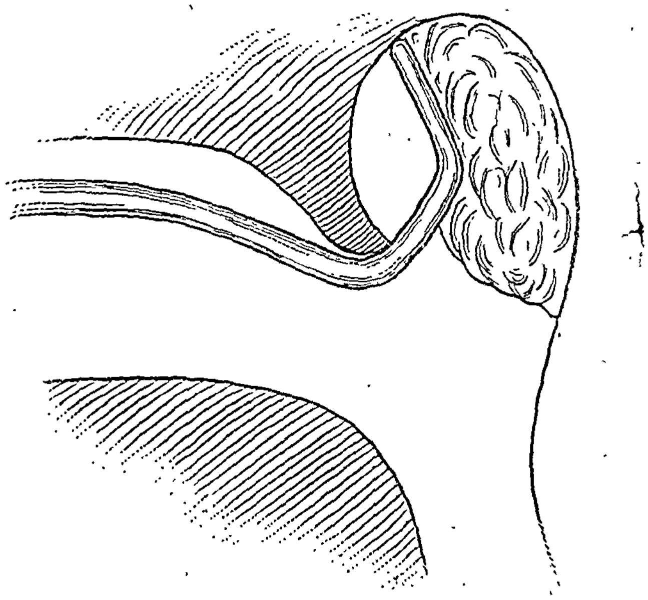

Fig. 5.—Curette in position.

Depressing the handle, the cutting edge will be brought in front of the adenoid growth and will be directed backward towards the posterior wall of the pharynx. (See Fig. 5). The patient's head held securely by the operator's left hand, the handle of the curette should be elevated so that the blade will be carred backward and downward, removing the growth with one stroke (see Fig. 6). In a few cases in which the hypertrophy is very extensive, having a broad base, you will be unable to remove the entire growth by one stroke, but the remaining portion can be removed by a subsequent one. Immediately after the removal of the instrument the patient's head should be carried forward over the basin so that the blood may escape by means of the nose and mouth.

The operation by means of this instrument is exceedingly simple and requires very little skill. The technique can be easily acquired by every careful surgeon.

There is some soreness of the parts and occasionally some difficulty in swallowing for a day or two following the operation. It is usually advisable, especially in children, to keep them in bed for a few hours, and they should be confined to the house for two or three days according to the weather. Solid food should not be allowed for the first forty-eight hours. There may be some slight elevation of temperature for a few days.

The improvement in breathing is marked, and immediate, in a majority of cases, while that of hearing and speech is farther delayed.

There is some danger of otitis media from the blood or discharges passing into the Eustachian tubes. For this reason the tympanic membrane should be carefully inspected daily until recovery has been complete. Should this accident occur, the external auditory meatus should be kept clean by means of a warm boric acid solution. Ear-ache, which is occasionally complained of, should be treated by means of counter irritation, and the continuous use of hot water and opium to the ear.

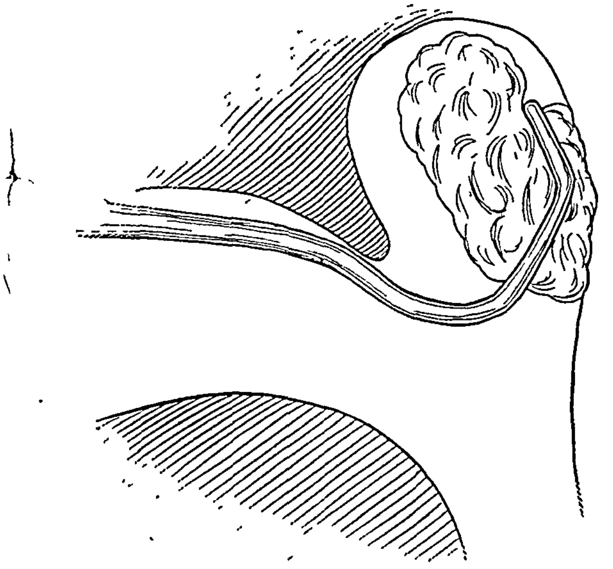

Fig. 6.—Enlargement partially removed.

In those cases in which there is some anterior obstruction, subsequent treatment should be directed towards its removal. When the hearing is not sufficiently improved, insufflation of the Eustachian tube should be performed from three to six times a week. Faulty speech is the most troublesome symptom to overcome, and is only cured by careful instruction by a competent teacher.

The patient should be taught to keep the mouth closed. For those who breathe through the mouth after all the obstructions have been removed, Löwenberg has suggested the use of a chin piece with tapes to tie over the head, thus keeping the mouth closed. The propriety of using any device of this kind is questionable, as nasal respiration is almost invariably adopted as soon as it is made possible.

In closing, allow me to say, I know of no operation in the domain of special surgery, in which the results are so satisfactory to all parties considered, as in the condition which I have just described. It should not, however, be undertaken except in those cases in which it is needed. The patient's general condition undergoes a marked change, which astonishes not only the parents and friends, but often the physician himself. I have yet to see any bad results from the operation, and when properly done, I believe it almost void of danger.

705 Venetian Building, Chicago.

PURULENT BRAIN DEPOSITS, AND PHLEBITIS AND THROMBOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

BY FRANK ALLPORT, M.D.,
OF MINNEAPOLIS, MINN.,
PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLOGY IN THE UNIVERSITY OF MINNESOTA, ETC.

(*Continued from page 580.*)

Case 111.—Treated by Moss of Heidelberg. Right ear. Acute otitis; pain in right forehead and temple, chills; constipation; somnolence; impaired vision; delirium; sudden rise and fall of temperature. Death.

Autopsy.—Thrombosis right lateral sinus and internal jugular vein. Phlebitis of emissary mastoid vein.

Case 112.—Treated by Moss of Heidelberg. Right ear. Chronic otorrhœa; intense pain in right side of head. Death.

Autopsy.—Thrombosis of sigmoid flexure. Thrombosis of right lateral sinus. Lepto-meningitis.

Case 113.—Treated by Moss of Heidelberg. Right ear. Chronic otorrhœa; chills; pain in occiput; vomiting. Death.

Autopsy.—Phlebitis and thrombosis of lateral sinus. Meningitis. Cholesteatoma in mastoid cells.

Case 114.—Treated by Moss of Heidelberg. Chronic otorrhœa; pain in ear, forehead and occiput; fever; œdema of temple; headache; stupor; spasms of upper extremities. Death.

Autopsy.—Phlebitis and thrombosis of lateral and superior petrosal sinuses. Circumscribed basilar meningitis.

Case 115.—Treated by Burckhardt-Merian. Age, one. Left ear. Chronic otorrhœa; external opening made over mastoid; vomiting: delirium; nose-bleed. Death.

Autopsy.—Tubercular meningitis- Thrombosis of left lateral sinus.

Case 115.—Transactions American Otological Society, 1885. Treated by C. J. Kipp. Female, age twenty-one. Left ear. Furuncle left meatus; pain in head. Death.

Autopsy.—Inflammation of arachnoid and pia-mater. Abscess anterior portion of cerebellum. Left auditory and facial nerves imbedded in pus. Pus in mastoid cells. Slight tympanic inflammation.

Case 117.—*Medical Correspond-Blatt von Wurttemburg*, 1889. Treated by Kœbel of Stuttgart. Chronic otorrhœa; pain; facial paralysis; mastoid opened; caries of cells, antrum and tympanum; pyæmia. Death.

Autopsy.—Carious openings into middle cerebral fossa and into transverse sinus. Phlebitis and thrombus of transverse sinus.

Case 118.—*Medical Record*, July 7, 1887. Treated by Roosa of New York City. Male, age forty-one. Right ear. Acute purulent otorrhœa; meningitic symptoms; chills; temperature medium; pulse low; improvement; Wildes' incision; delirium; pyæmia. Death.

Autopsy.—Sinuses filled with dark coagula. In the pia-mater was extensive fibrino-purulent exudation. Lateral ventricles dilated and filled with blood-stained serum. Necrosis of petrous, through roof of tympanum. Lateral sinus, carious.

Case 119.—Transactions American Otological Society. Treated by J. Orne Green. Male, age twenty-five. Chronic otorrhœa: deaf; dizziness; headache; diplopia; partial paralysis; coma. Death.

Autopsy.—Abscess tempero-sphenoidal lobe. Necrosis tegmen-tympani, and sinus connecting auditory canal and cerebral cavity.

Case 120.—Treatise on the Ear, by Roosa, page 532. Treated at New York Hospital. Left ear. Chronic otorrhœa; has had mastoid abscess when young; pain; high fever. Death.

Autopsy.—Pus under dura-mater and in mastoid cells. The entire temporal bone infiltrated with pus. Drum-head gone. Malleus, incus and part of the stapes gone.

Case 121.—Treatise on the Ear, by Roosa, page 532. Treated at New York Eye and Ear Infirmary. Right ear. Acute inflammation of middle ear and meatus; discharge; pain in right side of head; delirium; retention of urine; temperature and pulse medium. Death.

Autopsy.—Right optic nerve atrophied. The meninges at base of cerebellum, and upper part of spinal cord, were covered with lymph and sero-pus. Mastoid bone infiltrated with pus. Drum-head gone. Malleus and incus gone.

Case 122.—Treatise on the Ear, by Roosa. Treated by Cooper, of New Jersey. Male, age sixty-five. Right ear. Acute purulent otorrhœa; pain behind ear and in head; stupor. Death.

Autopsy.—Dura-mater congested, and lymph at base of brain. Pus at base of brain, extending to the medulla.

Case 123.—Transactions American Otological Society. Treated by Roosa of New York City. Male, age twenty-five. Right ear. Chronic otorrhœa; pain in head and ear; profuse discharge; temperature and pulse medium; chills; pleurisy; pneumonia; pain over lateral sinus; exophthalmus. Death.

Autopsy.—Thrombosis of right internal jugular. Pus in right lateral sinus. Drum-head and ossicles gone. Right lateral sinus carious.

Case 124.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. age sixty-six. Right ear. Chronic otorrhœa; deafness on one side; went to bed as usual; next morning paralysis of one side, also ptosis; paralysis persisted for some days; became giddy; had severe chills; drowsy; delirious at intervals; face flushed; head hot; convulsions; gradually sank and died.

Autopsy.—Abscess in centre of right cerebral hemisphere.

Case 125.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Male, age twenty. Chronic otorrhœa; head and neck rigidly curved forward, and spine curved; some rotary movements of the head; was unable to swallow. Death.

Autopsy.—Abscess in the pons varolii.

Case 126.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Male, age twenty-two. Chronic otorrhœa; sore throat for one week, and became generally ill; discharge from ear; chills; semi-comatose condition. Death.

Autopsy.—Abscess in middle lobe.

Case 127.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Female, age forty-one. Right ear. Chronic suppuration; paralysis of right half of face; constant pain on right side of head; drowsy; semi-comatose. Death.

Autopsy.—Abscess in the middle half of right lobe of cerebellum, communicating directly with the diseased portion of the temporal bone.

Carse 128.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton.—Male, age twenty-three. Right ear. chronic otorrhœa; caries of the temporal bone; chills; pain in the head; vomiting. Death.

Autopsy.—Abscess in the right lobe of cerebellum.

Case 129.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Male, age twenty-five. Right ear. Chronic otorrhœa; frontal headache; vertigo; delirium; paresis of left side; coma. Death.

Autopsy.—Abscess in the middle lobe of cerebrum on right side.

Case 130.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Female, age twenty-three. Right ear. Chronic otorrhœa; pain in right side of head and right ear; vomiting. Death.

Autopsy—Suppuration and sloughing of the middle lobe of right hemisphere.

Case 131.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Female, age twenty. Right ear. Purulent otorrhœa; paralysis of right seventh nerve; pain in head; pain on moving neck; chills; nausea; vomiting; sweating. Death.

Autopsy.—Abscess in the cerebellum.

Case 132.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Male, age thirteen. Chronic otorrhœa; syncope; convulsions with insensibility; pain in the head; nausea; delirium; convulsions; intense pain and cramp in left leg; coma. Death.

Autopsy.—Abscess under the posterior lobe of right hemisphere.

Case 133.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Male, age twenty-eight. Left ear. Chronic otorrhœa; delirium; coma. Death.

Autopsy.—Abscess in anterior and middle lobe of the left hemisphere. Caries of petrous bone connecting with abscess.

Case 134.—Extract from Treatise on the Ear, by Roosa. Male, age twenty-seven. Chronic otorrhœa; pain in head; paralysis of right side of face. Death from hæmorrhage (from lateral sinus).

Autopsy.—Dura-mater inflamed. A sloughing of brain tissue. Lateral sinus inflamed and sloughy.

(To be continued.)

SYMPHYSIOTOMY.—Dr. Charles Jewett, of Brooklyn, reports a case in the *Brooklyn Medical Journal*, in which he performed the operation of symphysiotomy with successful results. This is the first report of this operation being performed in this country.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a *delegate at an annual meeting of the Association is not* necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, NOVEMBER 19, 1892.

THE CODE OF ETHICS, CONSTITUTION AND BY-LAWS OF THE AMERICAN MEDICAL ASSOCIATION.

At the session of the American Medical Association held in Detroit, Mich., June 7, 1892, it was

Resolved, "That the President appoint a Committee of five to whom the Code of Ethics of this Association shall be referred for such changes or amendments as they may deem it wise to recommend, if they should decide that any change is required.

Resolved, "That this committee be instructed to determine and report to this Association for action thereon at its next annual meeting, such changes in its By-Laws or Constitution as in their judgment will properly liberalize the relations of this Association to the great body of the Medical Profession."

The Committee appointed was Henry D. Holton, Chairman, of Brattleboro, Vermont; H. D. Didama, Syracuse, N. Y.; Leartus Connor, Detroit, Mich.; Daniel T. Nelson, Chicago, Ill.; and Benjamin Lee, Philadelphia.

In order to perform its duties intelligently, this Committee desires that every practitioner should study anew the Code of Ethics and Constitution and By-Laws of the American Medical Association, that each would then inform the Chairman of this Committee on the following points:

1. Do you advise any change in these documents?
2. If you advise a change, please state specifically *what that change shall be?* In answering state the section or sections you would strike out, or add to, or amend. Kindly give the exact phraseology that would best meet your views in the changes you suggest.

Should you not have the documents in question at hand you can procure them for a trifling consideration from the Publication Office of the ASSOCIATION JOURNAL, 68 Wabash Avenue, Chicago, Ill.

Please give this your earliest attention, and send your wishes to the Chairman of the Committee, Dr. Henry D. Holton, Brattleboro, Vermont, at a date not later than January 1, 1893.

Very respectfully yours,
HENRY D. HOLTON,
H. D. DIDAMA,
LEARTUS CONNOR,
DANIEL T. NELSON,
BENJAMIN LEE.

Committee on Revision of the Code of Ethics and Constitution and By-Laws of the American Medical Association.

CODE OF MEDICAL ETHICS OF THE AMERICAN MEDICAL ASSOCIATION.

(*Originally Adopted at the Adjourned Meeting of the National Medical Convention in Philadelphia, May, 1847.*)

ART. I.—*Duties of physicians to their patients.*

§ 1. A physician should not only be ever ready to obey the calls of the sick, but his mind ought also to be imbued with the greatness of his mission, and the responsibility he habitually incurs in its discharge. These obligations are the more deep and enduring, because there is no tribunal other than his own conscience to adjudge penalties for carelessness or neglect. Physicians should, therefore, minister to the sick with due impressions of the importance of their office; reflecting that the ease, the health, and the lives of those committed to their charge, depend on their skill, attention, and fidelity. They should study, also, in their deportment, so to unite *tenderness* with *firmness*, and *condescension* with *authority*, as to inspire the minds of their patients with gratitude, respect, and confidence.

§ 2. Every case committed to the charge of a physician should be treated with attention, steadiness, and humanity. Reasonable indulgence should be granted to the mental imbecility and caprices of the sick. Secrecy and delicacy, when required by peculiar circumstances, should be strictly observed; and the familiar and confidential intercourse to which physicians are admitted in their professional visits should be used with discretion, and with the most scrupulous regard to fidelity and honor. The obligation of secrecy extends beyond the period of professional services; none of the privacies of personal and domestic life, no infirmity of disposition or flaw of character observed during professional attendance should ever be divulged by the physician except when he is imperatively required to do so. The force and necessity of this obligation are indeed so great that, professional men have, under certain circumstances, been protected in their observance of secrecy by courts of justice.

§ 3. Frequent visits to the sick are in general requisite, since they enable the physician to arrive at a more perfect knowledge of the disease—to meet promptly every change which may occur, and also tend to preserve the confidence of the patient. But unnecessary visits are to be avoided, as they give useless anxiety to the patient, tend to diminish the authority of the physician, and render him liable to be suspected of interested motives.

§ 4. A physician should not be forward to make gloomy prognostications, because they savor of empiricism, by magnifying the importance of his services in the treatment or cure of the disease. But he should not fail, on proper occasions, to give to the friends of the patient timely notice of danger when it really occurs; and even to the patient himself, if absolutely necessary. This office, however, is so peculiarly alarming when executed by him, that it ought to be declined whenever it can be assigned to any other person of sufficient judgment and delicacy. For the physician should be the minister of hope and comfort to the sick; that, by such cordials to the drooping spirit, he may smooth the bed of death, revive expiring life, and counteract the depressing influence of those maladies which often disturb the tranquility of the most resigned in their last moments. The life of a sick person can be shortened not only by the acts, but also by the words or the manner of a physician. It is, therefore a sacred duty to guard himself carefully in this respect, and to avoid all things which have a tendency to discourage the patient and to depress his spirits.

§ 5. A physician ought not to abandon a patient because the case is deemed incurable; for his attendance may continue to be highly useful to the patient, and comforting to the relatives around him, even in the last period of a fatal malady, by alleviating pain and other symptoms, and by soothing mental anguish. To decline attendance under such circumstances, would be sacrificing to fanciful delicacy and mistaken liberality, that moral duty which is independent of, and far superior to, all pecuniary consideration.

§ 6. Consultations should be promoted in difficult or protracted cases, as they give rise to confidence, energy, and more enlarged views in practice.

§ 7. The opportunity which a physician not unfrequently enjoys of promoting and strengthening the good resolutions of his patients, suffering under the consequences of vicious conduct, ought never to be neglected. His counsels, or even remonstrances, will give satisfaction, not offense, if they be proffered with politeness, and evince a genuine love of virtue, accompanied by a sincere interest in the welfare of the person to whom they are addressed.

ART. II.—*Obligations of patients to their physicians.*

§ 1. The members of the medical profession, upon whom is enjoined the performance of so many important and arduous duties toward the community, and who are required to make so many sacrifices of comfort, ease, and health, for the welfare of those who avail themselves of their services, certainly have a right to expect and require, that their patients should entertain a just sense of the duties which they owe to their medical attendants.

§ 2. The first duty of a patient is to select as his medical adviser one who has received a regular professional education. In no trade or occupation do mankind rely on the skill of an untaught artist; and in medicine, confessedly the most difficult and intricate of the sciences, the world ought not to suppose that knowledge is intuitive.

§ 3. Patients should prefer a physician whose habits of life are regular, and who is not devoted to company, pleasure, or to any pursuit incompatible with his professional obligations. A patient should, also, confide the care of himself and family, as much as possible, to one physician; for a medical man who has become acquainted with the peculiarities of constitution, habits, and predispositions of those he attends, is more likely to be successful in his treatment than one who does not possess that knowledge.

A patient who has thus selected his physician should always apply for advice in what may appear to him trivial cases, for the most fatal results often supervene on the slightest accidents. It is of still more importance that he should apply for assistance in the forming stage of violent diseases; it is to a neglect of this precept that medicine owes much of the uncertainty and imperfection with which it has been reproached.

§ 4. Patients should faithfully and unreservedly communicate to their physician the supposed cause of their disease. This is the more important, as many diseases of a mental origin simulate those depending on external causes, and yet are only to be cured by ministering to the mind diseased. A patient should never be afraid of thus making his physician his friend and adviser; he should always bear in mind that a medical man is under the strongest obligations of secrecy. Even the female sex should never allow feelings of shame or delicacy to prevent their disclosing the seat, symptoms and causes of complaints peculiar to them. However commendable a modest reserve may be in the common occurrences of life, its strict observance in medicine is often attended with the most serious consequences, and a patient may sink under a painful and loathsome disease, which might have been readily prevented had timely intimation been given to the physician.

§ 5. A patient should never weary his physician with a tedious detail of events or matters, as not appertaining to his disease. Even as relates to his actual symptoms, he will convey much more real information by giving clear answers to interrogatories, than by the most minute account of his own framing. Neither should he obtrude upon his physician the details of his business nor the history of his family concerns.

§ 6. The obedience of a patient to the prescriptions of his physician should be prompt and implicit. He should never permit his own crude opinions as to their fitness to influence his attention to them. A failure in one particular may render an otherwise judicious treatment dangerous, and even fatal. This remark is equally applicable to diet, drink, and exercise. As patients become convalescent they are very apt to suppose that the rules prescribed for them may be disregarded, and the consequence, but too often, is a relapse. Patients should never allow themselves to be persuaded to take any medicine whatever, that may be recommended to them by the self-constituted doctors and doctresses who are so frequently met with, and who pretend to possess infallible remedies for the cure of every disease. However simple some of their prescriptions may appear to be, it often happens that they are productive of much mischief, and in all cases they are injurious, by contravening the plan of treatment adopted by the physician.

§ 7. A patient should, if possible, avoid even the *friendly visits of a physician* who is not attending him—and when he does receive them, he should never converse on the subject of his disease, as an observation may be made, without any intention of interference, which may destroy his confidence in the course he is pursuing, and induce him to neglect the directions prescribed to him. A patient should never send for a consulting physician without the express consent of his own medical attendant. It is of great importance that physicians should act in concert; for, although their modes of treatment may be attended with equal success when applied singly, yet conjointly they are very likely to be productive of disastrous results.

§ 8. When a patient wishes to dismiss his physician, justice and common courtesy require that he should declare his reasons for so doing.

§ 9. Patients should always, when practicable, send for their physician in the morning, before his usual hour of going out; for, by being early aware of the visits he has to pay during the day, the physician is able to apportion his time in such a manner as to prevent an interference of engagements. Patients should also avoid calling on their medical advisor unnecessarily during the hours devoted to meals or sleep. They should always be in readiness to receive the visits of their physician, as the detention of a few minutes is often of serious inconvenience to him.

§ 10. A patient should, after his recovery, entertain a just and endearing sense of the value of the services rendered him by his physician; for these are of such a character, that no mere pecuniary acknowledgement can repay or cancel them.

OF THE DUTIES OF PHYSICIANS TO EACH OTHER, AND TO THE PROFESSION AT LARGE.

ART. I.—*Duties for the support of professional character.*

§ 1. Every individual, on entering the profession, as he becomes thereby entitled to all its privileges and immunities, incurs an obligation to exert his best abilities to maintain its dignity and honor, to exalt its standing, and to extend the bounds of its usefulness. He should, therefore, observe strictly such laws as are instituted for the government of its members; should avoid all contumelious and sarcastic remarks relative to the faculty as a body; and while, by unwearied diligence, he resorts to every honorable means of enriching the science, he should entertain a due respect for his seniors, who have, by their labors, brought it to the elevated condition in which he finds it.

§ 2. It is not in accord with the interests of the public or the honor of the profession that any physician or medical teacher should examine or sign diplomas or certificates of proficiency for, or otherwise be specially concerned with, the graduation of persons whom they have good reason to believe intend to support and practice any exclusive and irregular system of medicine.

§ 3. There is no profession from the members of which greater purity of character and a higher standard of moral excellence are required, than the medical; and to attain such eminence is a duty every physician owes alike to his profession and to his patients. It is due to the latter, as without it he cannot command their respect and confidence, and to both, because no scientific attainments can compensate for the want of correct moral principles. It is also incumbent upon the faculty to be temperate in all things, for the practice of physic requires the unremitting exercise of a clear and vigorous understanding; and, on emergencies, for which no professional man should be unprepared, a steady hand, an acute eye, and an unclouded head may be essential to the well-being, and even to the life, of a fellow-creature.

§ 4. It is derogatory to the dignity of the profession to resort to public advertisements, or private cards, or handbills, inviting the attention of individuals affected with particular diseases—publicly offering advice and medicine to the poor gratis, or promising radical cures; or to publish cases and operations in the daily prints, or suffer such publications to be made; to invite laymen to be present at operations, to boast of cures and remedies, to adduce certificates of skill and success, or to perform any other similar acts. These are the ordinary practices of empirics, and are highly reprehensible in a regular physician.

§ 5. Equally derogatory to professional character is it for a physician to hold a patent for any surgical instrument or medicine; or to dispense a secret *nostrum*, whether it be the composition of exclusive property of himself or others. For, if such nostrum be of real efficacy, any concealment regarding it is inconsistant with beneficence and professional liberality; and if mystery alone give it value and importance, such craft implies either disgraceful ignorance or fraudulent avarice. It is also reprehensible for physicians to give certificates attesting the efficacy of patent or secret medicines, or in any way to promote the use of them.

ART. II.—*Professional services of physicians to each other.*

§ 1. All practitioners of medicine, their wives, and their children while under the paternal care, are entitled to the gratuitous services of any one or more of the faculty residing near them, whose assistance may be desired. A physician afflicted with disease is usually an incompetent judge of his own case; and the natural anxiety and solicitude which he experiences at the sickness of a wife, a child, or any one who, by the ties of consanguinity, is rendered peculiarly dear to him, tend to obscure his judgment, and produce timidity and irresolution in his practice. Under such circumstances, medical men are peculiarly dependent upon each other, and kind offices and professional aid should always be cheerfully and gratuitously afforded. Visits ought not, however, to be obtruded officiously; as such unasked civility may give rise to embarrassment, or interfere with that choice on which confidence depends. But, if a distant member of the faculty, whose circumstances are affluent, request attendance, and an honorarium be offered, it should not be declined; for no pecuniary obligation ought to be imposed, which the party receiving it would not wish to incur.

ART. III.—*Of the duties of physicians as respects vicarious offices.*

§ 1. The affairs of life, the pursuit of health, and the various accidents and contingencies to which a medical man is peculiarly exposed, sometimes require him temporarily to withdraw from his duties to his patients, and to request some of his professional brethren to officiate for him. Compliance with this request is an act of courtesy, which should always be performed with the utmost consideration for the interest and character of the family physician, and when exercised for a short period all the pecuniary obligations for such services should be awarded to him. But if a member of the profession neglect his business in quest of pleasure and amusement, he cannot be considered as entitled to the advantages of the frequent and long-continued exercise of this fraternal courtesy without awarding to the physician who officiates the fees arising from the discharge of his professional duties.

In obstetrical and important surgical cases, which give rise to unusual fatigue, anxiety and responsibility, it is just that the fees accruing therefrom should be awarded to the physician who officiates.

ART. IV.—*Of the duties of physicians in regard to consultations.*

§ 1. A regular medical education furnishes the only presumptive evidence of professional abilities and acquirements, and ought to be the only acknowledged right of an individual to the exercise and honors of his profession. Nevertheless, as in consultations the good of the patient is the sole object in view, and this is often dependent on personal confidence, no intelligent regular practitioner, who has a license to practice from some medical board of known and acknowledged respectability, recognized by the Association, and who is in good moral and professional standing in the place in which he resides, should be fastidiously excluded from fellowship, or his aid refused in consultation, when it is requested by the patient. But no one can be considered as a regular practitioner or a fit associate in consultation, whose practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology and organic history.

§ 2. In consultations, no rivalship or jealousy should be indulged; candor, probity, and all due respect should be exercised toward the physician having charge of the case.

§ 3. In consultations, the attending physician should be the first to propose the necessary questions to the sick; after which the consulting physician should have the opportunity to make such further inquiries of the patient as may be necessary to satisfy him of the true character of the case. Both physicians should then retire to a private place for deliberation; and the one first in attendance should communicate the directions agreed upon to the patient or his friends, as well as any opinions which it may be thought proper to express. But no statement or discussion of it should take place before the patient or his friends, except in the presence of all the faculty attending, and by their common consent; and no *opinions* or *prognostications* should be delivered which are not the result of previous deliberation and concurrence.

§ 4. In consultations, the physician in attendance should deliver his opinion first; and when there are several consulting, they should deliver their opinions in the order in which they have been called. No decision, however, should restrain the attending physician from making such variations in the mode of treatment as any subsequent unexpected change in the character of the case may demand. But such variation, and the reasons for it, ought to be carefully detailed at the next meeting in consultation. The same privilege belongs also to the consulting physician if he is sent for in an emergency, when the regular attendant is out of the way, and similar explanations must be made by him at the next consultation.

§ 5. The utmost punctuality should be observed in the visits of physicians when they are to hold consultations together, and this is generally practicable, for society has been considerate enough to allow the plea of a professional engagement to take precedence of all others, and to be an ample reason for the relinquishment of any present occupation. But as professional engagements may sometimes interfere, and delay one of the parties, the physician who first arrives should wait for his associate a reasonable period, after which the consultation should be considered as postponed to a new appointment. If it be the attending physician who is present, he will, of course, see the patient and prescribe; but if it be the consulting one, he should retire, except in case of emergency, or when he has been called from a considerable distance, in which latter case he may examine the patient, and give his opinion *in writing* and *under seal*, to be delivered to his associate.

§ 6. In consultations, theoretical discussions should be avoided, as occasioning perplexity and loss of time. For there may be much diversity of opinion concerning speculative points, with perfect agreement in those modes of practice which are founded, not on hypothesis, but on experience and observation.

§ 7. All discussions in consultation should be held as secret and confidential. Neither by words nor manner should any of the parties to a consultation assert or insinuate that any part of the treatment pursued did not receive his assent. The responsibility must be equally divided between the medical attendants—they must equally share the credit of success as well as the blame of failure.

§. 8. Should an irreconcilable diversity of opinion occur when several physicians are called upon to consult together, the opinion of the majority should be considered as decisive; but if the numbers be equal on each side, then the decision should rest with the attending physician. It may, moreover, sometimes happen that two physicians cannot agree in their views of the nature of a case, and the treatment to be pursued. This is a circumstance much to be deplored, and should always be avoided, if possible, by mutual concessions, as far as they can be justified by a conscientious regard for the dictates of judgment. But in the event of its occurrence, a third physician should, if practicable, be called to act as umpire; and, if circumstances prevent the adoption of his course, it must be left to the patient to select the physician in which he is most willing to confide. But, as every physician relies upon the rectitude of his judgment, he should, when left in the minority, politely and consistently retire from any further deliberation in the consultation, or participation in the management of the case.

§ 9. As circumstances sometimes occur to render a *special consultation* desirable, when the continued attendance of two physicians might be objectionable to the patient, the member of the faculty whose assistance is required in such cases should sedulously guard against all future unsolicited attendance. As such consultations require an extraordinary portion of both time and attention, at least a double honorarium may be reasonably expected.

§ 10. A physician who is called upon to consult, should observe the most honorable and scrupulous regard for the character and standing of the practitioner in attendance; the practice of the latter, if necessary, should be justified as far as it can be, consistently with a conscientious regard for truth, and no hint or insinuation should be thrown out which could impair the confidence reposed in him, or affect his reputation. The consulting physician should also carefully refrain from any of those extraordinary attentions or assiduities which are too often practiced by the dishonest for the base purpose of gaining applause, or ingratiating themselves into the favor of families and individuals.

ART. V.—*Duties of physicians in cases of interference.*

§ 1. Medicine is a liberal profession, and those admitted into its ranks should found their expectations of practice upon the extent of their qualifications, not on intrigue or artifice.

§ 2. A physician, in his intercourse with a patient under the care of another practitioner, should observe the strictest caution and reserve. No meddling inquiries should be made—no disingenuous hints given relative to the nature and treatment of his disorder; nor any course of conduct pursued that may directly or indirectly tend to diminish the trust reposed in the physician employed.

§ 3. The same circumspection and reserve should be observed when, from motives of business or friendship, a physician is prompted to visit an individual who is under the direction of another practitioner. Indeed, such visits should be avoided, except under peculiar circumstances; and when they are made, no particular inquiries should be instituted relative to the nature of the disease, or the remedies employed, ing advice and medicine to the poor gratis, or promising radical cures; or to publish cases and operations in the daily prints, or suffer such publications to be made; to invite laymen to be present at operations, to boast of cures and remedies, to adduce certificates of skill and success, or to perform any other similar acts. These are the ordinary practices of empirics, and are highly reprehensible in a regular physician.

§ 5. Equally derogatory to professional character is it for a physician to hold a patent for any surgical instrument or medicine; or to dispense a secret *nostrum*, whether it be the composition of exclusive property of himself or others. For, if such nostrum be of real efficacy, any concealment regarding it is inconsistant with beneficence and professional liberality; and if mystery alone give it value and importance, such craft implies either disgraceful ignorance or fraudulent avarice. It is also reprehensible for physicians to give certificates attesting the efficacy of patent or secret medicines, or in any way to promote the use of them.

ART. II.—*Professional services of physicians to each other.*

§ 1. All practitioners of medicine, their wives, and their children while under the paternal care, are entitled to the gratuitous services of any one or more of the faculty residing near them, whose assistance may be desired. A physician afflicted with disease is usually an incompetent judge of his own case; and the natural anxiety and solicitude which he experiences at the sickness of a wife, a child, or any one who, by the ties of consanguinity, is rendered peculiarly dear to him, tend to obscure his judgment, and produce timidity and irresolution in his practice. Under such circumstances, medical men are peculiarly dependent upon each other, and kind offices and professional aid should always be cheerfully and gratuitously afforded. Visits ought not, however, to be obtruded officiously; as such unasked civility may give rise to embarrassment, or interfere with that choice on which confidence depends. But, if a distant member of the faculty, whose circumstances are affluent, request attendance, and an honorarium be offered, it should not be declined; for no pecuniary obligation ought to be imposed, which the party receiving it would not wish to incur.

ART. III.—*Of the duties of physicians as respects vicarious offices.*

§ 1. The affairs of life, the pursuit of health, and the various accidents and contingencies to which a medical man is peculiarly exposed, sometimes require him temporarily to withdraw from his duties to his patients, and to request some of his professional brethren to officiate for him. Compliance with this request is an act of courtesy, which should always be performed with the utmost consideration for the interest and character of the family physician, and when exercised for a short period all the pecuniary obligations for such services should be awarded to him. But if a member of the profession neglect his business in quest of pleasure and amusement, he cannot be considered as entitled to the advantages of the frequent and long-continued exercise of this fraternal courtesy without awarding to the physician who officiates the fees arising from the discharge of his professional duties.

In obstetrical and important surgical cases, which give rise to unusual fatigue, anxiety and responsibility, it is just that the fees accruing therefrom should be awarded to the physician who officiates.

ART. IV.—*Of the duties of physicians in regard to consultations.*

§ 1. A regular medical education furnishes the only presumptive evidence of professional abilities and acquirements, and ought to be the only acknowledged right of an individual to the exercise and honors of his profession. Nevertheless, as in consultations the good of the patient is the sole object in view, and this is often dependent on personal confidence, no intelligent regular practitioner, who has a license to practice from some medical board of known and acknowledged respectability, recognized by the Association, and who is in good moral and professional standing in the place in which he resides, should be fastidiously excluded from fellowship, or his aid refused in consultation, when it is requested by the patient. But no one can be considered as a regular practitioner or a fit associate in consultation, whose practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology and organic history.

§ 2. In consultations, no rivalship or jealousy should be indulged; candor, probity, and all due respect should be exercised toward the physician having charge of the case.

§ 3. In consultations, the attending physician should be the first to propose the necessary questions to the sick; after which the consulting physician should have the opportunity to make such further inquiries of the patient as may be necessary to satisfy him of the true character of the case. Both physicians should then retire to a private place for deliberation; and the one first in attendance should communicate the directions agreed upon to the patient or his friends, as well as any opinions which it may be thought proper to express. But no statement or discussion of it should take place before the patient or his friends, except in the presence of all the faculty attending, and by their common consent; and no *opinions* or *prognostications* should be delivered which are not the result of previous deliberation and concurrence.

§ 4. In consultations, the physician in attendance should deliver his opinion first; and when there are several consulting, they should deliver their opinions in the order in which they have been called. No decision, however, should restrain the attending physician from making such variations in the mode of treatment as any subsequent unexpected change in the character of the case may demand. But such variation, and the reasons for it, ought to be carefully detailed at the next meeting in consultation. The same privilege belongs also to the consulting physician if he is sent for in an emergency, when the regular attendant is out of the way, and similar explanations must be made by him at the next consultation.

§ 5. The utmost punctuality should be observed in the visits of physicians when they are to hold consultations together, and this is generally practicable, for society has been considerate enough to allow the plea of a professional engagement to take precedence of all others, and to be an ample reason for the relinquishment of any present occupation. But as professional engagements may sometimes interfere, and delay one of the parties, the physician who first arrives should wait for his associate a reasonable period, after which the consultation should be considered as postponed to a new appointment. If it be the attending physician who is present, he will, of course, see the patient and prescribe; but if it be the consulting one, he should retire, except in case of emergency, or when he has been called from a considerable distance, in which latter case he may examine the patient, and give his opinion *in writing* and *under seal*, to be delivered to his associate.

§ 6. In consultations, theoretical discussions should be avoided, as occasioning perplexity and loss of time. For there may be much diversity of opinion concerning speculative points, with perfect agreement in those modes of practice which are founded, not on hypothesis, but on experience and observation.

§ 7. All discussions in consultation should be held as secret and confidential. Neither by words nor manner should any of the parties to a consultation assert or insinuate that any part of the treatment pursued did not receive his assent. The responsibility must be equally divided between the medical attendants—they must equally share the credit of success as well as the blame of failure.

§ 8. Should an irreconcilable diversity of opinion occur when several physicians are called upon to consult together, the opinion of the majority should be considered as decisive; but if the numbers be equal on each side, then the decision should rest with the attending physician. It may, moreover, sometimes happen that two physicians cannot agree in their views of the nature of a case, and the treatment to be pursued. This is a circumstance much to be deplored, and should always be avoided, if possible, by mutual concessions, as far as they can be justified by a conscientious regard for the dictates of judgment. But in the event of its occurrence, a third physician should, if practicable, be called to act as umpire; and, if circumstances prevent the adoption of his course, it must be left to the patient to select the physician in which he is most willing to confide. But, as every physician relies upon the rectitude of his judgment, he should, when left in the minority, politely and consistently retire from any further deliberation in the consultation, or participation in the management of the case.

§ 9. As circumstances sometimes occur to render a *special consultation* desirable, when the continued attendance of two physicians might be objectionable to the patient, the member of the faculty whose assistance is required in such cases should sedulously guard against all future unsolicited attendance. As such consultations require an extraordinary portion of both time and attention, at least a double honorarium may be reasonably expected.

§ 10. A physician who is called upon to consult, should observe the most honorable and scrupulous regard for the character and standing of the practitioner in attendance; the practice of the latter, if necessary, should be justified as far as it can be, consistently with a conscientious regard for truth, and no hint or insinuation should be thrown out which could impair the confidence reposed in him, or affect his reputation. The consulting physician should also carefully refrain from any of those extraordinary attentions or assiduities which are too often practiced by the dishonest for the base purpose of gaining applause, or ingratiating themselves into the favor of families and individuals.

ART. V.—*Duties of physicians in cases of interference.*

§ 1. Medicine is a liberal profession, and those admitted into its ranks should found their expectations of practice upon the extent of their qualifications, not on intrigue or artifice.

§ 2. A physician, in his intercourse with a patient under the care of another practitioner, should observe the strictest caution and reserve. No meddling inquiries should be made—no disingenuous hints given relative to the nature and treatment of his disorder; nor any course of conduct pursued that may directly or indirectly tend to diminish the trust reposed in the physician employed.

§ 3. The same circumspection and reserve should be observed when, from motives of business or friendship, a physician is prompted to visit an individual who is under the direction of another practitioner. Indeed, such visits should be avoided, except under peculiar circumstances; and when they are made, no particular inquiries should be instituted relative to the nature of the disease, or the remedies employed, but the topics of conversation should be as foreign to the case as circumstances will admit.

§ 4. A physician ought not to take charge of or prescribe for a patient who has recently been under the care of another member of the faculty in the same illness, except in cases of sudden emergency, or in consultation with the physician previously in attendance, or when the latter has relinquished the case, or been regularly notified that his services are no longer desired. Under such circumstances, no unjust and illiberal insinuations should be thrown out in relation to the conduct or practice previously pursued, which should be justified so far as candor and regard for truth and probity will permit; for it often happens that patients become dissatisfied when they do not experience immediate relief, and, as many diseases are naturally protracted, the want of success, in the first stage of treatment, affords no evidence of a lack of professional knowledge and skill.

§ 5. When a physician is called to an urgent case, because the family attendant is not at hand, he ought, unless his assistance in consultation be desired, to resign the care of the patient to the latter immediately on his arrival.

§ 6. It often happens in case of sudden illness, or of recent accidents and injuries, owing to the alarm and anxiety of friends, that a number of physicians are simultaneously sent for. Under these circumstances, courtesy should assign the patient to the first who arrives, who should select from those present any additional assistance that he may deem necessary. In all such cases, however, the practitioner who officiates should request the family physician, if there be one, to be called, and, unless his further attendance be requested, should resign the case to the latter on his arrival.

§ 7. When a physician is called to the patient of another practitioner, in consequence of the sickness or absence of the latter, he ought, on the return or recovery of the regular attendant and with the consent of the patient, to surrender the case.

[The expression, "patient of another practitioner," is understood to mean a patient who may have been under the charge of another practitioner at the time of the attack of sickness, or departure from home of the latter, or who may have called for his attendance during his absence or sickness, or in any other manner given it to be understood that he regarded the said physician as his regular medical attendant.]

§ 8. A physician, when visiting a sick person in the country, may be desired to see a neighboring patient who is under the regular direction of another physician, in consequence of some sudden change or aggravation of symptoms. The conduct to be pursued on such an occasion is to give advice adapted to present circumstances; to interfere no further than is absolutely necessary with the general plan of treatment; to assume no future direction unless it be expressly desired; and, in this last case, to request an immediate consultation with the practitioner previously employed.

§ 9. A wealthy physician should not give advice *gratis* to the affluent; because his doing so is an injury to his professional brethren. The office of a physician can never be supported as an exclusively beneficent one; and it is defrauding, in some degree, the common funds for its support, when fees are dispensed with which might justly be claimed.

§ 10. When a physician who has been engaged to attend a case of midwifery is absent, and another is sent for, if delivery is accomplished during the attendance of the latter, he is entitled to the fee, but should resign the patient to the practitioner first engaged.

ART. VI.—*Of differences between physicians.*

§ 1. Diversity of opinion and opposition of interest may, in the medical as in other professions, sometimes occasion controversy and even contention. Whenever such cases unfortunately occur, and cannot be immediately terminated, they should be referred to the arbitration of a sufficient number of physicians or a *court-medical.*

§ 2. As peculiar reserve must be maintained by physicians toward the public, in regard to professional matters, and as there exist numerous points in medical ethics and etiquette through which the feelings of medical men may be painfully assailed in their intercourse with each other, and which cannot be understood or appreciated by general society, neither the subject-matter of such differences nor the adjudication of the arbitrators should be made public, as publicity in a case of this nature may be personally injurious to the individuals concerned, and can hardly fail to bring discredit on the faculty.

ART. VII.—*Of pecuniary acknowledgments.*

Some general rules should be adopted by the faculty, in every town or district, relative to *pecuniary acknowledgments* from their patients; and it should be deemed a point of honor to adhere to these rules with as much uniformity as varying circumstances will admit.

OF THE DUTIES OF THE PROFESSION TO THE PUBLIC, AND OF THE OBLIGATIONS OF THE PUBLIC TO THE PROFESSION.

ART. I.—*Duties of the profession to the public.*

§ 1. As good citizens, it is the duty of physicians to be ever vigilant for the welfare of the community, and to bear their part in sustaining its institutions and burdens; they should also be ever ready to give counsel to the public in relation to matters especially appertaining to their profession, as on subjects of medical police, public hygiene, and legal medicine, It is their province to enlighten the public in regard to quarantine regulations; the location, arrangement, and dietaries of hospitals, asylums, schools, prisons, and similar institutions; in relation to the medical police of towns, as drainage, ventilation, etc.; and in regard to measures for the prevention of epidemic and contagious diseases; and when pestilence prevails, it is their duty to face the danger, and to continue their labors for the alleviation of the suffering, even at the jeopardy of their own lives.

§ 2. Medical men should also be always ready, when called on by the legally constituted authorities, to enlighten coroners' inquests and courts of justice on subjects strictly medical—such as involve questions relating to sanity, legitimacy, murder by poisons or other violent means, and in regard to the various other subjects embraced in the science of Medical Jurisprudence. But in these cases, and especially where they are required to make a *post-mortem* examination, it is just, in consequence of the time, labor, and skill required, and the responsibility and risk they incur, that the public should award them a proper honorarium.

§ 3. There is no profession by the members of which eleemosynary services are more liberally dispensed than the medical, but justice requires that some limits should be placed to the performance of such good offices. Poverty, professional brotherhood, and certain of the public duties referred to in the first section of this article, should always be recognized as presenting valid claims for gratuitous services; but neither institutions endowed by the public or by rich individuals, societies for mutual benefit, for the insurance of lives or for analogous purposes, nor any profession or occupation, can be admitted to possess such privilege. Nor can it be justly expected of physicians to furnish certificates of inability to serve on juries, to perform militia duty, or to testify to the state of health of persons wishing to insure their lives, obtain pensions, or the like, without a pecuniary acknowledgement. But to individuals in indigent circumstances, such professional services should always be cheerfully and freely accorded.

§ 4. It is the duty of physicians, who are frequent witnesses of the enormities committed by quackery, and the injury to health and even destruction of life caused by the use of quack medicines, to enlighten the public on these subjects, to expose the injuries sustained by the unwary from the devices and pretensions of artful empirics and imposters. Physicians ought to use all the influence which they may possess, as professors of Colleges of Pharmacy, and by exercising their option in regard to the shops to which their prescriptions shall be sent, to discourage druggists and apothecaries from vending quack or secret medicines, or from being in any way engaged in their manufacture or sale

ART. II.—*Obligations of the public to physicians.*

§ 1. The benefits accruing to the public, directly and indirectly, from the active and unwearied beneficence of the profession, are so numerous and important, that physicians are justly entitled to the utmost consideration and respect from the community. The public ought likewise to entertain a just appreciation of medical qualifications; to make a proper discrimination between true science and the assumptions of ignorance and empiricism; to afford every encouragement and facility for the acquisition of medical education—and no longer to allow the statute-books to exhibit the anomaly of exacting knowledge from physicians, under a liability to heavy penalties, and of making them obnoxious to punishment for resort to the only means of obtaining it.

EXPLANATORY DECLARATIONS.

WHEREAS, Persistent misrepresentations have been and still are being made concerning certain provisions of the Code of Ethics of this Association, by which many in the community, and some even in the ranks of the profession are led to believe those provisions exclude persons from professional recognition simply because of differences of opinions or doctrines; therefore

1. *Resolved*, That clause first, of Art. IV, in the National Code of Medical Ethics, is not to be interpreted as excluding from professional fellowship, on the ground of differences in doctrine or belief, those who in other respects are entitled to be members of the regular medical profession. Neither is there any other article or clause of the said Code of Ethics that interferes with the exercise of the most perfect liberty of individual opinion and practice.

2. *Resolved*, That it constitutes a voluntary disconnection or withdrawal from the medical profession proper, to assume a name indicating to the public a sectarian, or exclusive system of practice, or to belong to an association or party antagonistic to the general medical profession.

3. *Resolved*, That there is no provision in the National Code of Medical Ethics in any wise inconsis- with the broadest dictates of humanity, and that the article of the Code which relates to consultations cannot be correctly interpreted as interdicting, under any circumstances, the rendering of professional services whenever there is a pressing or immediate need of them. On the contrary, to meet the emergencies occasioned by disease or accident, and to give a helping hand to the distressed without unnecessary delay is a duty fully enjoined on every member of the profession, both by the letter and the spirit of the entire Code.

But no such emergencies or circumstances can make it necessary or proper to enter into formal professional consultations with those who have voluntarily disconnected themselves from the regular medical profession, in the manner indicated by the preceding resolution.

N. S. DAVIS, of Chicago,
A. Y. P. GARNETT, of Washington,
H. F. CAMPBELL, of Augusta, Ga.,
AUSTIN FLINT, of New York,

On motion of Dr. Brodie, the resolutions were unanimously adopted.

On motion of Dr. Keller, it was unanimously agreed that the resolutions be added as an explanatory addendum in all future publications of the Code.

CONSTITUTION AND BY-LAWS OF THE AMERICAN MEDICAL ASSOCIATION.

(Revised to March 28, 1891.)

PLAN OF ORGANIZATION FOR A NATIONAL MEDICAL ASSOCIATION.

WHEREAS, The Medical Convention, held in the City of New York, in May, 1846, have declared it expedient "for the medical profession of the United States to institute a National Medical Association;" and,

Inasmuch as an institution so conducted as to give frequent, united and emphatic expression to the views and aims of the medical profession in this country, must at all times have a beneficial influence, and supply more efficient means than have hitherto been available here for cultivating and advancing medical knowledge; for elevating the standard of medical education; for promoting the usefulness, honor, and interests of the medical profession; for enlightening and directing public opinion in regard to the duties, responsibilities, and requirements of medical men; for exciting and encouraging emulation and concert of action in the profession, and for facilitating and fostering friendly intercourse between those who are engaged in it: therefore, be it

Resolved, In behalf of the medical profession of the United States, that the members of the Medical Convention, held in Philadelphia, in May, 1847, and all others who, in pursuit of the objects above mentioned, are to unite with or succeed them, constitute a National Medical Association; and that for the organization and management of the same, they adopt the following *Regulations:*[1]

I.—TITLE OF THE ASSOCIATION.

This institution shall be known and distinguished by the name and title of "The American Medical Association."

II.—MEMBERS.

The members of this institution shall collectively represent and have cognizance of the common interests of the medical profession in every part of the United States, and shall hold their appointment to membership either as delegates from local institutions, as members by invitation, as permanent members, or members by application.

The *Delegates* shall receive their appointment from permanently organized State medical societies, and such county and district medical societies as are recognized by representation in their respective State societies, and from the medical department of the Army and Navy of the United States, and the Marine Hospital Service of the United States.

Each delegate shall hold his appointment for one year, and until another is appointed to succeed him. and shall participate in all the business and affairs of the Association.

Each State, county and district medical society entitled to representation, shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number. *Provided*, however, that the number of delegates from any particular State, Territory, county, city or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of this Association. The Medical Staffs of the Army and Navy shall be entitled to four delegates each. The Marine-Hospital Service of the United States shall be entitled to one delegate.

No individual who shall be under sentence of expulsion or suspension from any State or local medical society of which he may have been a member, or whose name shall have been, for non.payment of dues, dropped from the rolls of the same, shall be received as a delegate to this Association, or be allowed any of the privileges of a member, until he shall have been relieved from the said sentence or disability by such State or local Society, or shall have paid up all arrears of membership; nor shall any person not a member and supporter of a local medical society, where such a one exists, be eligible to membership in the American Medical Association

No one expelled from this Association shall at any time thereafter be received as a delegate or member, unless by a three-fourths vote of the members present at the meeting to which he is sent, or at which he is proposed.

Members by Invitation shall consist of practitioners of reputable standing from sections of the United States not otherwise represented at the meeting. They shall receive their appointment by invitation of the meeting, after an introduction from, and being vouched for by, at least three of the members present, or three of the absent permanent members. They shall hold their connection with the Association until the close of the annual session at which they are received, and shall be entitled to participate in all its affairs, as in the case of delegates, except the right to vote.

---

[1] Revised to date.

The *Permanent Members* shall consist of all those who have served in the capacity of delegates, and of such other members as may receive the appointment by unanimous vote, and shall continue such so long as they remain in good standing in the body from which they were sent as delegates, and comply with the requirements of the By-laws of the Association. Permanent members shall at all times be entitled to attend the meetings, and participate in the affairs of the Association, so long as they shall continue to conform to its regulations, but without the right of voting; and when not in attendance, they shall be authorized to grant letters of introduction to reputable practitioners of medicine residing in their vicinity, who may wish to participate in the business of the meeting, as provided for members by invitation.

Members by Application shall consist of such members of the State, county and district medical societies entitled to representation in this Association as shall make application for admission, in writing, to the Treasurer, and accompany said application with a certificate of good standing, signed by the President and Secretary of the society of which they are members, and the amount of the annual fee, five dollars. They shall have their names upon the roll, and have all the rights and privileges accorded to permanent members, and shall retain their membership on the same terms.

Every member elect, prior to the permanent organization of the annual meeting, or before voting on any question after the meeting has been organized, must exhibit his credentials to the proper committee, and sign these regulations, inscribing his name and address in full, specifying in what capacity he attends, and, if a delegate, the title of the institution from which he has received his appointment.

III.—MEETINGS.

The regular meetings of the Association shall be held annually. The place of meeting shall be determined, with the time of meeting for each next successive year, by vote of the Association.

IV.—OFFICERS.

The officers of the Association shall be a President, four Vice-Presidents, one Permanent and one Assistant Secretary, a Treasurer, and Librarian. They shall be nominated by a special committee of one member from each State represented at the meeting, and shall be elected by vote on a general ticket.

Each officer except the Permanent Secretary, shall hold his appointment for one year, and until another is elected to succeed him. The Permanent Secretary shall hold his appointment until removed by death, resignation, or a vote of two-thirds of the members present at a regular annual meeting.

The President and Vice-Presidents shall assume the functions of their respective offices at the beginning of the annual meeting next succeeding their election; all other officers shall enter upon their duties immediately after their election.

The President shall preside at the meetings, preserve order and decorum in debate, give a casting vote when necessary, and perform all the other duties that custom and parliamentary usage may require.

The Vice-presidents, when called upon, shall assist the President in the performance of his duties, and during the absence, or at the request of the President, one of them shall officiate in his place.

The Permanent Secretary shall record the minutes and authenticate the proceedings; give due notice of the time and place of each next ensuing annual meeting; notify all members of committees of their appointment, and of the duties assigned to them; hold correspondence with other permanently organized medical societies, both domestic and foreign: and carefully preserve the archives and unpublished transactions of the Association.

The Assistant Secretary shall aid the Permanent Secretary in recording and authenticating the proceeding of the Association; serve as a member of the Committee of Arrangements, and perform all the duties of Permanent Secretary temporarily whenever that office shall be vacant, either by death, resignation, or removal.

The Treasurer shall have the immediate charge and management of the funds and property of the Association. He shall give to the Board of Trustees bonds for the safe keeping and proper use and disposal of his trust. And through the same Board he shall present his accounts, duly authenticated, at every regular meeting.

The Librarian shall receive and preserve all the property in books, pamphlets, journals, and manuscripts presented to or acquired by the Association, record their titles in a book prepared for the purpose and acknowledge the receipt of the same.

V.—STANDING COMMITTEES.

The Committee of Arrangments shall, if no sufficient reasons prevent, be mainly composed of seven members, of whom the Assistant Secretary shall be one, residing in the place at which the Association is to hold its next annual meeting; and shall be required to provide suitable accommodations for the meeting, to verify and report upon the credentials of membership, to receive and announce all essays and memoirs voluntarily communicated, either by members of the Association, or by others through them, and to determine the order in which such papers are to be read and considered.

The Board of Trustees shall consist of nine members, three of whom shall be elected annually, on the nomination of the Nominating Committee, and shall serve for three years. It shall be the duty of this Board to provide for and superintend the publication and distribution of all such proceedings, transactions, and memoirs of the Association as may be ordered to be published, in such manner as the Association may direct, and in doing this it shall have authority to appoint an editor and such assistants, and determine their salaries, and procure and control such materials as may be necessary for the accomplishment of the work assigned to it. To further facilitate its work, it shall be the duty of the Secretaries of the Association, and of the several sections during each annual meeting, or as soon thereafter as practicable, to deliver to the Board, or such editor or agent as it shall appoint, all such records of proceedings, reports, addresses, papers and other documents as may have been ordered for publication either in the general sessions or in the Sections. All moneys received by the Board of Trustees, or its agents, resulting from the discharge of the duties assigned them, must be paid to the Treasurer of the Association, and all orders on the Treasurer for disbursements of money in any way connected with the work of publication, must be endorsed by the President of the Board of Trustees. It shall be the further duty of the said Board of Trustees to hold the official bond of the Treasurer for the faithful execution of his office, to annually audit and authenticate his accounts, and present a statement of the same in its annual report to the Association during the year, the number of copies still on hand, and the amount of all other property belonging to the Association, under its control, with such suggestions as it may deem necessary.

VI.—FUNDS AND APPROPRIATIONS.

Funds shall be raised by the Association for meeting its current expenses and awards from year to year, but never with the view of creating a permanent income from investments. Funds may obtained by an equal assessment of not more than ten dollars annually, on each of the delegates and permanent members; by voluntary contributions for specific objects; and by the sale and disposal of publications, or of works prepared for publication.

The funds may be appropriated for defraying the expenses of the Permanent Secretary in maintaining the necessary correspondence of the Association; for publication; for enabling the Standing Committees to fulfill their respective duties, conduct their correspondence, and procure the materials necessary for the completion of their stated annual reports; for the encouragement of scientific investigation by prizes and awards of merit; and for defraying the expenses incidental to specific investigations under the instruction of the Association, where such investigations have been accompanied with an order on the Treasurer to supply the funds necessary for carrying them into effect.

VII.—THE SECTIONS AND GENERAL BUSINESS COMMITTEE.

That each Section of this Association shall elect an Executive Committee of three members, who shall be chosen from among those who have been in attendance upon the sessions of the Section for at least two years; to serve one, two, and three years respectively; and that thereafter the retiring Chairman of the Section shall take the place upon the Executive Committee of the retiring member of the Committee. It shall be the duty of the Executive Committee, in conjunction with the Chairman and Secretary, to give especial attention to the interests of their own Section.

These Executive Committees of the Sections so formed shall constitute the General Business Committee of the Association. They shall hold daily meetings during the sessions of the Association, and all matters of business not provided for by the Committee of Arrangements, the Board of Trustees, the Judicial Council, the Committee of American Medical Necrology and Special Committees shall be referred to them without debate.

It shall be the duty of the General Business Committee to give especial attention to the interests of the Association, and to promote the welfare of the various sections; to consider all matters of business referred to it by the Association and report upon them at the earliest possible moment, when the Association may adopt or reject the report as it may deem best.

All Sections or parts of Sections of the Constitution or By-Laws of the Association not in harmony with this amendment are hereby repealed.

VIII.—PROVISION FOR AMENDMENT.

No amendment or alteration shall be made in any of these articles, except at the annual meeting next subsequent to that at which such amendment or alteration may have been proposed; and then only by the voice of three-fourths of all the delegates in attendance.

Provided, however, that when an amendment is is properly under consideration, and an amendment is offered thereto, germane to the subject, it shall be in order, and if adopted, shall have the same standing and force as if proposed at the preceding meeting meeting of the Association.

BY-LAWS.

I.—ORDER OF BUSINESS.

The order of business at the annual meetings of the American Medical Association shall at all times be subject to the vote of three-fourths of all the members in attendance; and, until permanently altered, except when for a time suspended, it shall be as follows, namely:

1. The calling of the meeting to order by the Pres-

ident elected the preceding year, or, in his absence' by one of the Vice-Presidents.

2. The report of the Committee of Arrangements on the credentials of members, after the latter have registered their names and addresses, and the titles of the institutions which they represent.

3. The reception of members by invitation.

4. The election of permanent members.

5. The reading of notes from absentees.

6. The hearing of the annual address of the President.

7. The reception of the reports of all special committees and voluntary communications, and their reference to the appropriate Sections.

8. The appointment of the committee of one from each State represented, to nominate officers of the Association, and to fill the standing committees.

9. The reading and consideration of the reports of Standing Committees, of Publication, on Prize Essays, and of Chairmen of Sections.

10. Resolutions introducing new business, and instructions to the permanent committees.

11. The selection of the next place of meeting.

12. The Report of the Nominating Committee, and the election of officers of the Association.

13. Reports from the several Sections.

14. Reading of the minutes by the Secretary.

15. Unfinished and miscellaneous business.

16. Adjournment.

II.—SECTIONS.

The general meetings of the Association shall be restricted to the morning sessions; and the afternoon sessions, commencing at three o'clock, shall be devoted to the hearing of reports and papers and their consideration, in the following *Sections*:—

1. Practical Medicine and Physiology.
2. Obstetrics and Diseases of Women.
3. Surgery and Anatomy.
4. State Medicine.
5. Ophthalmology.
6. Diseases of Children.
7. Dental and Oral Surgery.
8. Medical Jurisprudence and Neurology.
9. Dermatology and Syphilis.
10. Laryngology and Otology.
11. Materia Medica and Pharmacy.

On the second day of each annual meeting each Section shall nominate its own officers to serve for the next ensuing year, their duties to commence with the close of the annual meeting at which they are nominated, and to continue until their successors are appointed.

The Section on State Medicine shall be composed of one member from each State, one from the Army and one from the Navy of the United States, representing, as far as practicable, the State Boards of Health. The officers of this Section to be also designated by the Committee on Nominations.

The Chairman of each Section shall prepare an address on the recent advances in the branches belonging to his Section, including such suggestions in regard to improvements or methods of work as he may regard important, and present on the first day of the annual session the same to the Section over which he presides. The reading of such address not to occupy more than forty minutes.

It shall be the duty of every member of the Association who proposes to present a paper or report to any one of the Sections, to forward either the paper, or a *title* indicative of its contents, and its *length*, to the Chairman of the Committee of Arrangements at least one month before the annual meeting at which the paper or report is to be read. It shall also be the duty of the Chairman and Secretary of each Section to communicate the same information to the Chairman of the Committee of Arrangements concerning such papers and reports as may come into their possession or knowledge, for their respective Sections, the same length of time before the annual meeting. And the Committee of Arrangements shall determine the order of reading or presentation of all such papers, and announce the same in the form of a programme for the use of all members attending the annual meeting. Such programme shall also contain the rules specified in the By-laws and Ordinances concerning the consideration and disposal of all papers in the Sections.

No paper shall be read before either of the Sections, the reading of which occupies more than twenty minutes. Such papers shall be referred by the Section to subcommittees specially appointed for their examination. The subcommittees shall be allowed thirty days for their examination; at the end of which time they shall forward the papers to the Board of Trustees, with such recommendations as they may deem proper. The authors of such papers, however, may read abstracts before the Section within the allotted twenty minutes. No member shall address the Section more than once upon the same subject, nor speak longer than fifteen minutes without unanimous consent.

All papers presented directly to the Association, and other matters, may, at the discretion of the Association, be referred to the various Sections for their consideration and report.

III.—STANDING COMMITTEES.

The following are the Standing Committees of the Association, to be filled by the Committee on Nominations, and to report at the next annual meeting subsequent to their appointment, namely: Committee of Arrangements, Board of Trustees, and Committee on American Medical Necrology.

The *Board of Trustees* shall append to each volume of the *Transactions* hereafter published, a copy of the Constitution, By-laws and Code of Ethics of the tion and distribution of all such proceedings, transactions, and memoirs of the Association as may be ordered to be published, in such manner as the Association may direct, and in doing this it shall have authority to appoint an editor and such assistants, and determine their salaries, and procure and control such materials as may be necessary for the accomplishment of the work assigned to it. To further facilitate its work, it shall be the duty of the Secretaries of the Association, and of the several sections during each annual meeting, or as soon thereafter as practicable, to deliver to the Board, or such editor or agent as it shall appoint, all such records of proceedings, reports, addresses, papers and other documents as may have been ordered for publication either in the general sessions or in the Sections. All moneys received by the Board of Trustees, or its agents, resulting from the discharge of the duties assigned them, must be paid to the Treasurer of the Association, and all orders on the Treasurer for disbursements of money in any way connected with the work of publication, must be endorsed by the President of the Board of Trustees. It shall be the further duty of the said Board of Trustees to hold the official bond of the Treasurer for the faithful execution of his office, to annually audit and authenticate his accounts, and present a statement of the same in its annual report to the Association during the year, the number of copies still on hand, and the amount of all other property belonging to the Association, under its control, with such suggestions as it may deem necessary.

VI.—FUNDS AND APPROPRIATIONS.

Funds shall be raised by the Association for meeting its current expenses and awards from year to year, but never with the view of creating a permanent income from investments. Funds may obtained by an equal assessment of not more than ten dollars annually, on each of the delegates and permanent members; by voluntary contributions for specific objects; and by the sale and disposal of publications, or of works prepared for publication.

The funds may be appropriated for defraying the expenses of the Permanent Secretary in maintaining the necessary correspondence of the Association; for publication; for enabling the Standing Committees to fulfill their respective duties, conduct their correspondence, and procure the materials necessary for the completion of their stated annual reports; for the encouragement of scientific investigation by prizes and awards of merit; and for defraying the expenses incidental to specific investigations under the instruction of the Association, where such investigations have been accompanied with an order on the Treasurer to supply the funds necessary for carrying them into effect.

VII.—THE SECTIONS AND GENERAL BUSINESS COMMITTEE.

That each Section of this Association shall elect an Executive Committee of three members, who shall be chosen from among those who have been in attendance upon the sessions of the Section for at least two years; to serve one, two, and three years respectively; and that thereafter the retiring Chairman of the Section shall take the place upon the Executive Committee of the retiring member of the Committee. It shall be the duty of the Executive Committee, in conjunction with the Chairman and Secretary, to give especial attention to the interests of their own Section.

These Executive Committees of the Sections so formed shall constitute the General Business Committee of the Association. They shall hold daily meetings during the sessions of the Association, and all matters of business not provided for by the Committee of Arrangements, the Board of Trustees, the Judicial Council, the Committee of American Medical Necrology and Special Committees shall be referred to them without debate.

It shall be the duty of the General Business Committee to give especial attention to the interests of the Association, and to promote the welfare of the various sections; to consider all matters of business referred to it by the Association and report upon them at the earliest possible moment, when the Association may adopt or reject the report as it may deem best.

All Sections or parts of Sections of the Constitution or By-Laws of the Association not in harmony with this amendment are hereby repealed.

VIII.—PROVISION FOR AMENDMENT.

No amendment or alteration shall be made in any of these articles, except at the annual meeting next subsequent to that at which such amendment or alteration may have been proposed; and then only by the voice of three-fourths of all the delegates in attendance.

Provided, however, that when an amendment is is properly under consideration, and an amendment is offered thereto, germane to the subject, it shall be in order, and if adopted, shall have the same standing and force as if proposed at the preceding meeting meeting of the Association.

BY-LAWS.

I.—ORDER OF BUSINESS.

The order of business at the annual meetings of the American Medical Association shall at all times be subject to the vote of three-fourths of all the members in attendance; and, until permanently altered, except when for a time suspended, it shall be as follows, namely:

1. The calling of the meeting to order by the Pres-

ident elected the preceding year, or, in his absence, by one of the Vice-Presidents.

2. The report of the Committee of Arrangements on the credentials of members, after the latter have registered their names and addresses, and the titles of the institutions which they represent.

3. The reception of members by invitation.

4. The election of permanent members.

5. The reading of notes from absentees.

6. The hearing of the annual address of the President.

7. The reception of the reports of all special committees and voluntary communications, and their reference to the appropriate Sections.

8. The appointment of the committee of one from each State represented, to nominate officers of the Association, and to fill the standing committees.

9. The reading and consideration of the reports of Standing Committees, of Publication, on Prize Essays, and of Chairmen of Sections.

10. Resolutions introducing new business, and instructions to the permanent committees.

11. The selection of the next place of meeting.

12. The Report of the Nominating Committee, and the election of officers of the Association.

13. Reports from the several Sections.

14. Reading of the minutes by the Secretary.

15. Unfinished and miscellaneous business.

16. Adjournment.

II.—SECTIONS.

The general meetings of the Association shall be restricted to the morning sessions; and the afternoon sessions, commencing at three o'clock, shall be devoted to the hearing of reports and papers and their consideration, in the following *Sections*:—

1. Practical Medicine and Physiology.
2. Obstetrics and Diseases of Women.
3. Surgery and Anatomy.
4. State Medicine.
5. Ophthalmology.
6. Diseases of Children.
7. Dental and Oral Surgery.
8. Medical Jurisprudence and Neurology.
9. Dermatology and Syphilis.
10. Laryngology and Otology.
11. Materia Medica and Pharmacy.

On the second day of each annual meeting each Section shall nominate its own officers to serve for the next ensuing year, their duties to commence with the close of the annual meeting at which they are nominated, and to continue until their successors are appointed.

The Section on State Medicine shall be composed of one member from each State, one from the Army and one from the Navy of the United States, representing, as far as practicable, the State Boards of Health. The officers of this Section to be also designated by the Committee on Nominations.

The Chairman of each Section shall prepare an address on the recent advances in the branches belonging to his Section, including such suggestions in regard to improvements or methods of work as he may regard important, and present on the first day of the annual session the same to the Section over which he presides. The reading of such address not to occupy more than forty minutes.

It shall be the duty of every member of the Association who proposes to present a paper or report to any one of the Sections, to forward either the paper, or a *title* indicative of its contents, and its *length*, to the Chairman of the Committee of Arrangements at least one month before the annual meeting at which the paper or report is to be read. It shall also be the duty of the Chairman and Secretary of each Section to communicate the same information to the Chairman of the Committee of Arrangements concerning such papers and reports as may come into their possession or knowledge, for their respective Sections, the same length of time before the annual meeting. And the Committee of Arrangements shall determine the order of reading or presentation of all such papers, and announce the same in the form of a programme for the use of all members attending the annual meeting. Such programme shall also contain the rules specified in the By-laws and Ordinances concerning the consideration and disposal of all papers in the Sections.

No paper shall be read before either of the Sections, the reading of which occupies more than twenty minutes. Such papers shall be referred by the Section to subcommittees specially appointed for their examination. The subcommittees shall be allowed thirty days for their examination; at the end of which time they shall forward the papers to the Board of Trustees, with such recommendations as they may deem proper. The authors of such papers, however, may read abstracts before the Section within the allotted twenty minutes. No member shall address the Section more than once upon the same subject, nor speak longer than fifteen minutes without unanimous consent.

All papers presented directly to the Association, and other matters, may, at the discretion of the Association, be referred to the various Sections for their consideration and report.

III.—STANDING COMMITTEES.

The following are the Standing Committees of the Association, to be filled by the Committee on Nominations, and to report at the next annual meeting subsequent to their appointment, namely: Committee of Arrangements, Board of Trustees, and Committee on American Medical Necrology.

The *Board of Trustees* shall append to each volume of the *Transactions* hereafter published, a copy of the Constitution, By-laws and Code of Ethics of the

Association. It shall paint conspicuously, at the beginning of each volume of the *Transactions*, the following disclaimer, namely: The American Medical Association, although formally accepting and publishing the reports of the various standing committees, holds itself wholly irresponsible for the opinions, theories or criticisms therein contained, except when otherwise decided by special resolution.

The *Committee on American Medical Necrology* shall consist of one member for each State and Territory represented in the Association, whose duty it shall be to procure memorials of the eminent and worthy dead among the distinguished physicians of their respective States and Territories, and transmit them to the chairman of this committee on or before the 1st of April of each and every year.

IV.—THE PUBLICATION OF PAPERS AND REPORTS.

No report or other paper shall be entitled to publication in the volume for the year in which it shall be presented to the Association, unless it be placed in the hands of the Board of Trustees on or before the first day of July. It must also be so prepared as to require no material alteration or addition at the hands of its author.

Authors of papers are required to return their proofs within two weeks after their reception; otherwise they will be passed over and omitted from the volume.

Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association, and shall be published and sold for the exclusive benefit of the Association.

The Board of Trustees shall have full discretionary power to omit from the published *Transactions*, in part or in whole, any paper that may be referred to it by the Association, or either of the Sections, unless specially instructed to the contrary by vote of the Association.

V.—ASSESSMENTS.

The sum of five dollars shall be assessed annually, upon each delegate to the sessions of the Association, as well as upon each of its permanent members, whether attending or not, for the purpose of raising a fund to defray necessary expenses. The payment of this sum shall be required of the delegates and members in attendance upon the sessions of the Association previous to their taking their seats and participating in the business of the sessions. Permanent members, not in attendance, shall transmit their dues to the Treasurer.

Any permanent member who shall fail to pay his annual dues for three successive years, unless absent from the country, shall be dropped from the roll of permanent members, after having been notified by the Secretary of the forfeiture of his membership.

VI.—DELEGATES FROM THE MEDICAL STAFFS OF THE ARMY, NAVY, AND MARINE-HOSPITAL SERVICE.

Delegates representing the medical staffs of the United States Army and Navy, shall be appointed by the Chief of the Army and Navy Medical Bureaus, and the U. S. Marine-Hospital Service. The number of delegates so appointed shall be four from the Army medical officers, and an equal number from the Navy medical officers, and one from the Marine-Hospital Service.

VII.—DELEGATES TO FOREIGN MEDICAL SOCIETIES.

The President shall be authorized annually to appoint delegates to represent this Association at the meetings of the British Medical Association, the American Medical Society at Paris, and such other scientific bodies in Europe and other foreign countries as may be affiliated with us.

VIII.—DUTIES OF MEMBERS.

No one shall be permitted to address the Association, except he shall have first given his name and residence, which shall be distinctly announced from the chair, and the member may be required to go forward and speak from the stand, but not more than ten minutes at one time.

No one appointed on a special committee, who fails to report at the meeting next succeeding the one at which he is appointed, shall be continued on such committee, or appointed on any other, unless a satisfactory excuse is offered.

IX.—CONDITION EXCLUDING REPRESENTATION.

No State or Local Medical Society, or other organized institution, shall be entitled to representation in this Association that has not adopted the Code of Ethics; or that has intentionally violated or disregarded any article or clause of the same.

X.—OF THE PREVIOUS QUESTION.

When the previous question is demanded, it shall take at least twenty members to second it; and when the main question is under force of the previous question and negatived, the question shall remain under consideration the same as if the previous question had not been enforced.

XI.—JUDICIAL COUNCIL.

A council, consisting of twenty-one members, shall be appointed by the Nominating Committee, whose duty it shall be to take cognizance of, and decide, all questions of an ethical or judicial character that may arise in connection with the Association. Of the twenty-one members of the council first appointed the seven first named on the list shall hold office one year, and the second seven named shall hold office two years.

With these exceptions the term of office of members of the council shall be three years, seven being appointed by the Nominating Committee annually.

The said council shall organize by choosing a President and Secretary, and shall keep a permanent record of its proceedings. The decisions of said council on all matters referred to it by the Association shall be final, and shall be reported to the Association at the earliest moment.

All questions of a personal character, including complaints and protests, and all questions on credentials, shall be referred at once, after the report of Committee of Arrangements or other presentation, to the *Judicial Council*, and without discussion.

XII.—NEW BUSINESS.

No new business, resolutions by members, etc., shall be introduced at the general session of the Association except on the first and fourth days of meetings.

XIII.—OFFICERS AND COMMITTEES.

In the election of officers and appointment of committees by this Association and its President, they shall be confined to members and delegates present at the meeting, except in the Committee of Arrangements.

XIV.—ADDRESSES.

The Association shall annually elect, on the nomination of the Nominating Committee, three members of the profession, eminent in some of its departments, to deliver addresses in the general session of the next ensuing annual meeting—one on some topic or topics relating to general medicine, another relating to general surgery, and the third relating to public medicine, including under that head, hygiene, sanitation, prophylaxis, education and medical legislation, each of such addresses not to exceed one hour in its delivery.

The following resolution was adopted at the session of 1888:

That in future, each delegate or permanent member, shall, when he registers, also record the name of the Section, if any, that he will attend, and in which he will cast his vote for Section officers.

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the Secretaries *are, by special resolution,* requested to send to him annually, a corrected list of the membership of their respective Societies.

ORDINANCES.

Resolved, That the several Sections of this Association be requested, in the future, to refer no papers or reports to the Board of Trustees, except such as can be fairly classed under one of the three following heads, namely: 1. Such as may contain and establish *positively* new facts, modes of practice or principles of real value. 2. Such as may contain the results of well-devised original experimental researches. 3. Such as present so complete a review of the facts on any particular subject as to enable the writer to deduce therefrom legitimate conclusions of importance.

Resolved, That the several Sections be requested, in the future, to refer all such papers as may be presented to them for examination by this Association, that contain matter of more or less value, and yet cannot be fairly ranked under either of the heads mentioned in the foregoing resolution, back to their authors with the recommendation that they be published in such regular medical periodicals as said authors may select, with the privilege of placing at the head of such papers, "Read to the Section of the American Medical Association on the day of 18 ." (Vide *Transactions*, Vol. xvi, p. 40.)

Resolved, That instead of yearly reprinting the list of members of the American Medical Association, the Board of Trustees be instructed to prepare and print in the *Transactions* an alphabetical catalogue triennially, containing a complete list of the Permanent Members, with their names in full, designating their residences, the year of their admission, the offices they have held in the Association, and, in case of death or rejection, the date thereof. (Vide *Transactions*, Vol. xvii, p. 33.)

Resolved, That no report or other paper shall be presented to this Association unless it be so prepared that it can be put at once into the hands of the Permanent Secretary, to be transmitted to the Board of Trustees. (Vide *Transactious*, Vol. xvii, p. 27.)

Resolved, That the Permanent Secretary hereafter and from this date be authorized to draw a warrant upon the Treasurer for the expenses incurred in his attendance upon each session of the Association, and that the Treasurer is hereby instructed to pay the same. (Vide *Transactions*, Vol. xviii, p. 42.)

Resolved, That the faculties of the several medical colleges of the United States be recommended to announce explicitly in their annual announcements, circulars and advertisements that they will not receive certificates of time of study from irregular practitioners, and that they will not confer the degree upon any one who may acknowledge his intention to practice in accordance with any exclusive system. (Vide *Transactions*, Vol. xix, p. 31.)

Resolved, That those gentlemen who desire to report on special subjects, and will pledge themselves to report at the next meeting, be requested to send their names, and the subjects on which they desire to report to the Permanent Secretary. (Vide *Transactions*, Vol, xix, p. 42.)

Resolved, That hereafter the necessary expenses for rent of hall for general meetings and rooms for Sections to accommodate the annual meetings, and the necessary expenses for cards of membership, be paid out of the treasury of the Association. (Vide *Transactions*, Vol. xix, p. 42.)

Resolved, That each State Medical Society be requested to prepare an annual register of all the regular practitioners of medicine in their respective States, giving the name of the college in which they may have graduated, and date of diploma or license. (Vide *Transactions*, Vol. xx, p. 20.)

Resolved, That this Association recognizes specialties as proper and legitimate fields of labor.

Resolved, That specialists shall be governed by the same rules of professional etiquette as have been laid down for general practitioners.

Resolved, That it shall not be proper for specialists publicly to advertise themselves as such, or to assume any title not specially granted by a regularly chartered college.

Resolved, That private handbills addressed to members of the medical profession, or by cards in medical journals, calling the attention of professional brethren to themselves as specialists, be declared in violation of the Code of Ethics of the American Medical Association. (Vide *Transactions*, Vol. xx, p. 28.)

Resolved, That a committee of one be appointed residing at Washington, to render the Librarian of Congress such assistance as the interests of the Association may require. (Vide *Transactions*, Vol. xx, p. 28.)

WHEREAS, The proper construction of Art. IV, Sec. 1, Code of Ethics, A. M. A., having been called for, relative to consultation with irregular practitioners who are graduates of regular schools.

Resolved, That said Art. IV. Sec. 1, Code of Ethics, excludes all such practitioners from recognition by the regular profession. (Vide *Transactions*, Vol. xx, p. 30.)

Resolved, That if any member fail to reply for more than one year to the circular sent to him by the Board of Trustees he shall forfeit his right to the volume, and it shall revert to the Association, to be sold to any applicant at the current rates. (Vide *Transactions*, Vol. xxi, p. 30).

Resolved, That the Committee of Arrangements for the next ensuing meeting of this Association, and for all meetings thereafter, be directed to prepare a list of members present on a separate roll, for convenience and accuracy in calling the ayes and nays when the same shall be demanded. (Vide *Transactions*, Vol. xxi, p. 60.)

Resolved, That each year, until otherwise ordered, the President-elect and the Permanent Secretary be directed to appeal in the name of the Association to the authorities of each State where no State Board of Health exists, urging them to establish such boards. (Vide *Transactions*, Vol. xxvi, p. 50.)

Resolved, That the Permanent Secretary is hereby directed annually to report the names of States where boards of health exist, and also of those which decline to establish them; said report to form a part of the annual proceedings of the Association. (Vide *Transactions*, Vol. xxvi, p. 50.)

Resolved, That members of the medical profession who in any way aid or abet the graduation of medical students in irregular or exclusive systems of medicine, are deemed thereby to violate the spirit of the ethics of the American Medical Association. (Vide *Transactions*, Vol. xxvii. p. 48)

Resolved, 1. That the American Medical Association adopts the International Metric System, and will use it in its Transactions. (Vide *Transactions*, Vol. xxx. p. 44.)

2. Requests that those who present papers at its future meetings employ this system in their communications, or reprints thereof. (Vide *Transactions*, Vol. xxx, p. 44.)

3. Requests the medical boards of the hospitals and dispensaries to adopt the Metric System in prescribing and recording cases; and that the Faculties of the medical and pharmaceutic schools adopt it in their didactic, clinical, or dispensing departments. (Vide *Transactions*, Vol. xxx, p. 44.)

Resolved, That the President and Secretary of this Association are directed to annually petition Congress to enact a law which shall permit every person engaged in a scientific pursuit to import for his own use, free of duty, any one book or instrument appertaining to his special pursuit. (Vide *Transactions*, Vol. xxx, p. 45.)

Resolved, That the above named officers are further directed to urge the State Medical Societies and their auxiliary branches to aid this Association in accomplishing this purpose, by petitions to Congress, and by otherwise influencing Congressmen. (Vide *Transactions*, Vol. xxx, p. 45.)

Decision by Judicial Council: A gentleman who is not in affiliation with a County, District, or State Medical Society, where such organizations exist, is *not* entitled to be registered as a permanent member upon the claim of having been a delegate from a body not now entitled to representation in this body. (Vide *Transactions*, Vol. xxx, p. 57.)

Resolved, First. That a committee of five be appointed by the President of the Association, to be called the Standing Committee on "*Atmospheric* Conditions, and their relations to the prevalence of Diseases."

Second, That that committee be authorized to select such places as will best indicate atmospheric conditions in the more important climatic and sanitary district of the United States—not less than six, nor more than twelve—and establish therein a means for continuous observation and record of all appreciable conditions of atmosphere, according to the most approved methods, and of the origin and prevalence of all acute diseases.

Third. That the Committee, through their chairman, be authorized to draw upon the Treasurer of this Association for such sums as may be found necessary for the proper execution of the work assigned to it, the aggregate amount not to exceed $500, during the ensuing year, and that a detailed report of all sums drawn and expenditures made must be presented at the next annual meeting of the Association. (Vide *Transactions*, Vol. xxxii, p. 35.)

Resolved, That the regular graduates of such dental and oral schools and colleges as require of their students a standard of preliminary or general education, and a term of professional study equal to the best class of medical colleges of this country, and embrace in this curriculum all the fundamental branches of medicine; differing chiefly by substituting practical and clinical instruction in dental and oral medicine and surgery, in place of practical and clinical instruction in general medicine and surgery, be recognized as members of the regular profession of medicine, and eligible to membership in this Association on the same conditions and subject to the same regulations as other members. (See Journal of the Amer. Med. Ass'n, Vol. viii, p. 722.)

Whereas, It has been the unswerving policy of the Trustees for the publication of The Journal, to enlarge and increase the value of The Journal as fast as the income of the Association will permit, therefore

Resolved, That said Board of Trustees be a Standing Committee on Finance to which all propositions for the appropriation of money, made hereafter, shall be referred and reported upon before final action on the same by the Association. (See Journal of the Amer. Med. Ass'n, Vol. viii, p. 722, 1887.)

THE RECENT THERAPEUSIS OF DISEASES OF THE NERVOUS SYSTEM.

Though the attention and interest that were excited by Brown-Sequard's announcement of the discovery of a remedy for functional and asthenic disorders of the nervous system in hypodermatic injections of testicular juice has subsided, that physiologist has persisted in the experiments he was making with that substance in 1889, and in a recent memoir presented to the Academy of Sciences he made the following conclusions. First: In old men in whom the spermatic glands especially have lost their function, injections of testicular liquid may furnish that which is wanting for the potency of the nervous centres. Second: In all diseases feebleness may be combatted advantageously by injections of testicular liquid. The latter is most advantageously employed in pulmonary tuberculosis, locomotor ataxia, leprosy; anæmia, paralysis, etc. He persists in his former statement that during the administration of this substance the appetite and sleep return, micturition and defecation are more regularly performed, the genital functions are increased, and intellectual work becomes easier.

During the early part of this year Constantin Paul presented a memoir to the Paris Academy of Medicine, in which he stated that a sterilized ten per cent. solution of the gray substance of the brain of a sheep, injected in the cellular tissue in doses of five cubic centimetres, was well tolerated and exercised influences somewhat similar to those obtained by Brown-Sequard with testicular juice. A person receiving an injection becomes aware a short time subsequently of a power that he did not before possess; amyesthenia and muscular impotence rapidly diminish, and the patients are able to take long walks. After a few injections vertebral pains and spinal hyperæsthesia disappear, as do also the fulgerating pains in ataxics; insomnia and neurasthenic cephalalgia are cured; functional cerebral impotence is relieved; sexual impotence is ameliorated; and in chronic diseases functional processes are very much improved.

Brown-Sequard's results suggested that the alkaloid spermine, that Schreiter had obtained from sperm in 1878, might be the active principle in effecting the improvement he noted. Poehl has shown that this alkaloid may be obtained from the thyroid gland and cerebral substance as well as from the testicular juice. Victoroff claims that spermine is the active principle of Brown-Sequard's emulsion and that he has obtained equally good results from its administration, though the French physicians regard this claim as exaggerated.

The results obtained by Paul have also been observed by d'Arsonval, Babes, Cullerre, and others who have followed his directions.

More recently Dr. Crocq, *fils*, of Brussels, concluding that the phosphates were the important constituents in the testicular as well as the cerebral emulsions, has used in diseases for which the latter are employed, hypodermatic injections of phosphate of soda in doses varying from one-third of a grain to a grain daily or every other day. In a recent report in the *Gazette hebdomadaire de médicine et de chirurgie* Dr. Crocq states that after a few injections of phosphate of soda there is improvement in the appetite and in sleep; cephalalgia and other nervous pains disappear; physical and moral strength is invigorated; sexual desire is augmented; and in chronic diseases there is a general improvement in the condition of the patient.

The theory of dynamo-genesis advanced by Brown-Sequard, that, "in nature nothing creates itself nor loses itself; the law is as fatal for energy as it is for matter, and if energy is to be produced it is necessary to receive some portion of it," seems to have been accepted by Paul. But this law does not altogether explain Crocq, *fils's* results. And while the capability of these reporters can not be questioned, to the American mind the element of psychical therapeusis plays an important rôle in the results obtained. We would not, however, imply that this is altogether the case. For the improvement that has occurred in patients suffering with myxœdema in consequence of thyroid juice, suggests that the organic secretions contain complex products that may exercise decided influence on the organic functions of an individual into whose tissues they are injected.

MEDICAL EDUCATION FOR MEDICAL CULTURE.

The management of medical colleges has been too much dictated by the interests of the members of the faculty on the one hand, and the demands of medical students on the other. The interest of individual members of the faculty has thrown too much time and effort into clinical teaching, which has come to mean amphitheatre teaching. It has encouraged large classes and numerous alumni at the expense of scholarship. It has let down the bars of admission to medical schools and thrown them down still lower to let out the graduates. An ignorant and poorly equipped alumni multiplies consultations for an indulgent and popular faculty. Faculty management of medical schools has prevented the spirit of modern educational methods from gaining control here as it has done in technological schools elsewhere. The cry of "practical teaching" has been raised against every effort to secure aids to medical culture in medical schools. But the real issue has been utility to the faculty.

On the other hand, because, unfortunately, the doctor's degree has carried with it the right to practice medicine, there has been a constant demand on the part of students for the shortest possible course of study. It is humiliating to mention the length of the average college term to-day. It is still more humiliating to be obliged to say that only two such terms are required in certain portions of the country. The poor quality, so far as preliminary education is concerned, of the average medical student, has resulted in the demand for an educational pap suitable to his unevolved mental digestion. This again has precluded the idea of culture. It has militated against the refined and erudite teacher. It has fathered the rowdyism which still prevails in many medical schools.

Because our medical education has been guided by the interest of the faculty and the demand of presumptuous students, there has resulted a sort of medical teaching which has repulsed the educated and cultured students, and driven them into other professions and occupations. If the medical profession would secure a fair proportion of college-bred men, the medical schools must not only exclude the ignorant and untrained, but they must furnish a medical education of a better quality. The ridiculous stories with which too many medical lectures have been garnished must give place to far-reaching thoughts and lofty ideas. The minimum compulsory course must be supplemented by many elective, advanced courses. The short term of five or six months must be made a continuous series of shorter terms. The bare, dingy and silent walls of the medical school must become alive with suggestions of thought and work and aspiration. The locked-up museum and the antiquated show of a library must become living, growing, moving elements of medical education. The clinic for tragic and oratorical display, must become the laboratory of bedside instruction, bedside investigation and literary research. The working faculty of the medical schools must be reinforced by occasional lectures from thinkers and teachers in science, psychology and sociology. The medical school must no longer be the home of sordid self-interest, but the culture of a high-minded education must come in and abide.

SELECTIONS.

The Height of Rooms.—According to the *Practitioner* for March, the English Local Government Board has addressed a memorandum to the sanitary authorities of England concerning the height of rooms used for habitation, a recent law having conferred upon them authority to regulate the matter. It is held that it is unnecessary to appoint a maximum height, but, as low-pitched rooms are more difficult to ventilate than rooms of greater height, especially sleeping-rooms in which the occupants are not able during sleep to vary the conditions of air-movement through the rooms, a minimum height should be established. While a room may have sufficient floor space for a given number of people, whether this number will have enough breathing space to keep them in health will depend upon the height of the room. For example, if there is just enough breathing space when the height is eight feet, it is obvious that there will not be enough when the height is only seven feet. A minimum of nine feet is recommended, and the board will not approve of a smaller height than eight feet over the total area of the room. In a room of irregular height under the roof of a house there must be a mean height of eight feet.

Such a law does not seem to us to attain the desired end of the prevention of overcrowding; for, no matter how high a room may be, it is possible to so fill it with human beings that the breathing space will be inadequate for them, while a room less than eight feet high may be so well ventilated that the change of air compensates for the deficiency in cubic air space. Furthermore, in cold climates the difficulty for the poorer classes, for whose benefit this law was passed, to purchase enough fuel to heat their rooms and to keep them at a comfortable temperature, has always led to the stuffing of every crevice and cranny through which air could enter, and the advantage of high ceilings is vitiated.

If with such a law there was a provision defining the number of inhabitants to the minimum of cubic space, the end desired might be attained, provided there was a sufficient number of inspectors to detect and punish violations of the law.

The Transfusion of Nervous Matter in the Insane:—Dr. Constantin Paul has called attention, in a recently published memoir on the subject, to the value of what he calls nervous transfusion in the treatment of neurasthenia. The substance employed is the gray matter of the brain of a recently slaughtered sheep, allowed to macerate for twenty-four hours in twice its weight of pure glycerin, to which is subsequently added an equal quantity of boiled water. This is filtered, as well as prepared with all antiseptic precautions, and should be a clear, limpid, colorless, sterile liquid that will keep for a week with ordinary precautions. A drachm of this liquid is injected every second day into the thigh or the lumbar region, after the skin, syringe, and needle have been carefully disinfected. The injected liquid forms a small tumor that usually disappears within twenty-four hours.

In the *Gazette Médicale de Paris* for August 27th Dr. A. Cullerre reports the results that he has obtained with this substance in fourteen cases of insanity. In eight patients the results were good, in four there was a slight influence produced, and in two there was no effect. The author concludes that these transfusions are beneficial in asthenic as well as in tuberculous insane patients, and that they arouse the nutritive functions almost instantly. One of the first evidences of this result is an increase of appetite, a most desirable result in mental alienation, to combat sitiophobia. The reconstructive effects are rapid, muscular weakness disappears, the flesh increases, and all the organic functions are regulated. The psychopathic state in curable cases has been transitorily improved during a few hours immediately following the injections, but this improvement has not persisted. The author does not consider this conclusion definitive, as the major portion of his patients were incurably insane, and it is the rule in the curable forms of insanity for improvement in the mental condition to keep pace with nutritive improvement.—*New York Medical Journal.*

NECROLOGY.

A. Reeves Jackson, M.D.

One of the most highly esteemed and best beloved members of the medical profession died in Chicago, November 12.

The immediate cause of the death of Dr. Jackson was an apoplexy which is believed to have been the sequence to a poisoning of his system by an infective wound received while performing an operation some fifteen years ago.

Dr. Jackson has been so prominent a member of the medical profession for twenty-five years as to make his personal career familiar to all readers of our literature, to which he was a liberal contributor.

During the late War he served in the Army as an Assistant-Surgeon and as a Surgeon, rising to the position of Assistant Medical Director of the Army of Virginia. Soon after the close of the War he located in Chicago, where he early interested himself in founding the Woman's Hospital of Illinois, of which in 1871 he became its Surgeon in Chief. About this time he became identified with Rush Medical College as Lecturer on Gynecology.

In 1882, he became one of the founders of the College of Physicians and Surgeons of Chicago, of which he was President up to the time of his death.

The professional ambitions of Dr. Jackson were without doubt fully gratified. He stood with the limited few on the top rung of the ladder in his specialty, and becomingly accepted the honors so freely bestowed upon him by his fellows.

In the death of Dr. Jackson, the medical profession sustains the irreparable loss of a progressive leader. The laity and State an invaluable citizen. His wife and daughters have our profound sympathy in this their time of greatest grief and affliction. Dr. Jackson was a rare man. We ne'er shall see his like again.

BOOK REVIEWS.

An American Text-book of Surgery for Practitioners and Students. By Chas. H. Burnett, M.D., Phineas S. Connor, M.D., Frederick S. Dennis, M.D., William W. Keen, M.D., Charles B. Nancrede, M.D., Roswell Park, M.D., Lewis S. Pitcher, M.D., Nicholas Senn. M.D., Francis J. Shephard, M.D., Lewis A. Stinson, M.D., William A. Thompson, M.D., J. Collins Warren, M.D., and J. Wm. White, M.D. Edited by William W. Keen, M.D. LL.D., and J. William White, M.D., PhD. Cloth, 8vo., p. 1209. Philadelphia: W. B. Saunders. 1892.

This rather bulky volume has been prepared on a somewhat novel plan. We learn from the preface, that the proof-sheets of each article were submitted to all the authors for criticism and revision, and that " while it thus represents in general the views of all the authors *each individual author is free from absolute responsibility for any particular statement.*" The italics are ours, and while the motive may have been laudable, yet we cannot resist expression of regret that each article is unsigned. It may be old fashioned, but we vastly prefer a signed article to an anonymous one however excellent. The great authority of the well known surgeons whose names appear on the title page would surely not be lessened if it were known, that Prof. Burnett wrote the chapter on diseases of the ear and Prof. Thomson that on diseases of the eye, or that any other of the topics was written by some one of this brilliant galaxy whose special studies had made him a recognized authority on the subject. It is easy to hazard the conjecture that the chapter on Surgery of the Spine was written by Prof. White, that on the Head by Prof. Keen, and that on the Abdomen by Prof. Senn, and the whole book might be assigned without very much difficulty, but *cui bono?* The authors are "free from responsibilty for any particular statement and do not expect for anything that appears in this book to be individually quoted. It must not be understood that this is therefore wholly a publisher's book. It is on the contrary a work of great merit, despite the fact of its asserted irresponsibility.

The work as a whole is a great addition to American Surgical literature. The editors have been more than usually successful in preserving the unity of form and style, in articles from so many hands, and the articles themselves are prepared carefully to the date of publication. We notice an account of Fluhrer's gravity aluminium probe and Girdner's "telephone probe" and induction balances in the chapter on injuries of the head, but we regret to see an old *cause celebre,* misquoted on page 506 as the Vermont "Crowbar Case." This case was not one of injury by a "crowbar" but a "tamping iron" which identical object is specimen No. 3,106 in the Warren Anatomical Museum at Boston. The tamping iron in question is one and a quarter inches square at one end and gradually tapers to one-fourth of an inch in diameter at the other end; it is three feet seven inches long, and weighs thirteen and a quarter pounds. Our English friends so long declined to accept this case, that it would seem our "American" text-book should state it accurately. The skull itself is specimen No. 949 in the Warren Anatomical Museum, and bears visible testimony to the curious observer, that it was not a factor in a "Crowbar Case."

The fatal do nothing plan in cases of chest injury, is sharply contrasted with the bolder surgery of to-day on page 621, where a story is related that, "In one instance after a stab wound of the chest a man was allowed to die because it was held that a large vessel in his lung had been wounded and that his condition was consequently helpless. It was found later, however, that the bleeding all came from an intercostal artery, through which the man had bled to death into his *own* chest. In this case the result might have been very different had free incision been made and the source of the hæmorrhage sought for." This plain moral to a melancholy story is a rather mild echo of Guthrie's Golden Rule enunciated nearly forty years ago from the bloody fields of the Crimea; true now as then, "tie both ends of the bleeding vessel in the wound, enlarging the wound if necessary."

In this text-book the doctrine of microbic origin of many surgical diseases, and obstacles to repair is given its complete application to every topic, and the consequent enriching of surgical technique by new operations, and new therapeutical measures, receives full attention. It is no halting allegiance that our American Surgeons give the Microbic theory. They frankly state their faith and describe the procedures based thereon, with the positiveness born of experimental knowledge, and with results that justify the popular impression of the laity, that Surgery is a term almost synonymous with biological progress.

In conclusion our authors may be congratulated on the production of a work on Surgery which faithfully reflects the best teachings of the day, and which is undoubtedly destined to become deservedly popular with their countrymen.

TRANSACTIONS OF THE FORTY-SECOND ANNUAL MEETING OF THE ILLINOIS STATE MEDICAL SOCIETY. Held at Vandalia, May 17, 18, and 19, 1892.

The proceedings of this Society are so voluminous as to constitute a large book of almost five hundred pages of closely printed matter. The President, Dr. Charles C. Hunt of Dixon, called the meeting to order. The papers and discussions are valuable additions to the medical literature of the day.

Dr. E. Fletcher Ingals of Chicago, was elected President, and Dr. D. W. Graham re-elected Secretary for the ensuing year. Dr. Graham has for many years faithfully served the Society as its Secretary.

The next place of meeting and time will be in Chicago the third Tuesday in May, 1893.

TRANSACTIONS OF THE MEDICAL SOCIETY OF NEW JERSEY. The one hundred and twenty-sixth Annual Meeting.

It will be noted that this is one of the oldest organizations of physicians in this country. The meeting was convened at Atlantic City, June 28, 1892, with the President Dr. Elias J. Marsh in the Chair

The profession of New Jersey is to be congratulated on the completeness of its State organization. A pleasant feature of the occasion was the reception of delegates from other State societies, and the appointment of corresponding delegates to other State societies. This is a feature that warmly commends itself to the State societies of the Central and Western States. Such visitations to sister State societies is not only a social pleasure, but acts as an incentive to improvement in State and county organization.

After the reading of papers and discussions the society adjourned to meet at Spring Lake, N. J., on the Fourth Tuesday in June 1893. Dr. Geo. T. Welch, of Passaic having been elected President and Dr. William Pierson of Orange, Secretary.

HYDROTHERAPY AT SARATOGA. A Treatise on Natural Mineral Waters, by J. A. IRWIN, M.A., M.D. Cassell Publishing Company, New York.

As the title of this little work indicates, it is a description of the mineral springs of Saratoga, and their therapeutic application; we confess we do not see the justification of the sub-title, in which the volume is styled a treatise on natural mineral waters.

While there is much of value in the description of the qualities and application of the Saratoga waters, we regret that the writer did not confine himself to that subject exclusively, omitting the somewhat platitudinous utterances on the general subject of mineral waters and balneology. While there is nothing erroneous in the conclusions advanced, yet the elementary statements recommend it rather to the lay than professional reader.

The work is handsomely published and contains several wood cuts. The one on the first page, a picture of the author, shows a man of fine physique, clean cut features and high forehead.

TRANSACTIONS OF THE FIFTY-NINTH ANNUAL SESSION OF THE MEDICAL SOCIETY OF THE STATE OF TENNESSEE, Knoxville, April 12, 13, and 14, 1892.

The Society was called to order by the President, Dr. J. W. Penn, of Humboldt, Tenn. The subject of a more complete organization of the profession of the State was discussed, and with an evident determination on the part of those present to bring every regular practitioner in the State into membership relations with the Society, a condition that should, and will no doubt, be brought about as nearly as possible.

The papers read and discussed were of such a character as to be an attraction to any man who has a particle of professional pride.

Dr. C. W. Beaumont, of Clarksville, was elected President for the ensuing year. Dr. Daniel E. Nelson, of Chattanooga, was re-elected Secretary. Dr. Nelson has served the Society in this capacity for several years. The next place of meeting is Nashville, and time, the second Tuesday in April, 1893.

MISCELLANY.

ELEVENTH INTERNATIONAL MEDICAL CONGRESS.—(Rome, September 24 to October 1, 1893.) The American Sub-committee has the following membership: W. T. Briggs, Nashville, Tenn.; H. P. Bowditch, Boston, Mass.; S. C. Busey, Washington, D. C.; C. Cushing, San Francisco, Cal.; N. S. Davis, Chicago, Ill.; A. Jacobi, New York, Chairman; Norman W. Kingsley, DD.S., New York; Wm. Osler, Baltimore, Md.; Wm. Pepper, Philadelphia, Pa.; F. Peyre Porcher, Charleston, S. C.; Charles A. L. Reed, Cincinnati, O.; D. B. St. John Roosa, New York; Alex. J. C. Skene, Brooklyn, N. Y.; and James Stewart, Montreal, Can.

The Secretary-General informs the Committee, that the French Railway Company has offered to the members of the Congress a reduction of 50 per cent. on its fare.

DR. F. E. YEOKIN of Shreveport, La., has been elected Professor of Materia Medica and Therapeutics, and Nervous Diseases in the Gross Medical College.

OFFICIAL LIST OF CHANGES in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from November 5, 1892, to November 11, 1892.

Major Justus M. Brown, Surgeon U. S. A., is granted leave of absence for four months, with permission to apply for an extension of two months.

Capt. Eugene L. Swift, Asst. Surgeon U. S. A., is granted leave of absence for one month, to take effect upon expiration of present sick leave.

The Journal of the
American Medical Association

Vol. XIX. CHICAGO, NOVEMBER 26, 1892. No. 22.

ORIGINAL ARTICLES.

ADDRESS ON PHYSIOLOGY.

Delivered in the Section of Physiology and Dietetics, at the Forty-third annual meeting of the American Medical Association, held in Detroit, Mich., June, 1892.

C. H. A. KLEINSCHMIDT, Ph.D., M.D.,
CHAIRMAN OF SECTION, WASHINGTON, D.C.

Gentlemen: It is obviously the first and at the same time the most pleasant duty of your chairman, to congratulate the members of this Section on the fact, that the American Medical Association, at its forty-third annual meeting decided by an almost unanimous vote, to "omit the word physiology from the title of the Section on Practice of Medicine, and to form a new Section on Physiology and Dietetics." The wisdom of this action admits of no doubt, for the creation of this new Section enables those more especially interested in our branch of the medical sciences to present and discuss the results of their labors in this field under conditions much more favorable and satisfactory than could possibly be afforded while physiology was coördinated in the same Section with a branch, in which the usually superabundant, important and practical matters presented for consideration were apt to encroach upon those of a more specifically physiological bearing.

The next duty to be performed is to express to you the high appreciation of the honor conferred by being selected the first chairman of this important Section: yet, this appreciation is weighed with the feeling of regret, that the distinction was bestowed upon one, who but too well knows that he lacks many of the qualifications for his position. He hopes, however, that with the kind coöperation of his fellow members, his task will be rendered less weighty, and has the assurance that the results of your work will bear out the wisdom of the Association in the creation of the new Section.

Now, according to a by-law of our Association, it is made the function of the Chairman, to review in an address to be presented on the first day of the annual meeting, the recent advances made in the branches belonging to his Section, and in compliance with this rule, I now have the honor to present to your consideration a brief resumé of topics directly concerning us as physiologists. But in looking over the field of physiology as a whole, we find so much to claim a more than passing attention; so much active cultivation in every direction by so great a number of diligent investigators, that the task of presenting even a very concise synopsis of the work done in every part of the field appears altogether beyond the power of your reporter, in view of the vast amount of material accumulated in the literature of the year, an abundance so great as to become a very *embarras de richesses*. Hence it has been deemed advisable to confine the selection to the progress made in the physiology of the nervous system, partly because of a personal predeliction, but mainly because of the full recognition of the fact, that the activity of the nervous system underlies, regulates, and modifies directly or indirectly all vital functions whatsoever. Thus any discussion or investigation of the functions of the *working organs* so-called, can never be complete, unless allied to a consideration of the force calling them into play, to an investigation of the nerve-mechanism exciting, inhibiting or in some other way modifying them; and it has been said with perfect truth, that a complete history of the physiology of the nervous system would almost represent a history of physiology in general. In thus selecting, what appears to him the most interesting branch of physiology, your reporter can not, at the same time, close his eyes to the fact, that he is about to engage in the recital of what must necessarily prove a twice told tale to his hearers, and he also feels, that he runs the great risk of omitting to mention topics, that may possess the highest value in the opinions of some, while laying what may be called undue stress on those, that in the eyes of others may seem to be entitled to less consideration. Trusting, however, to your kind indulgence, he hopes that the imperfect sketch about to be offered may contain at least some food for thought, and a few points of interest to the members of the Section.

The functions of the cerebro-spinal axis as a whole are discussed in his usual brilliant style by Richardson (*Asclepiad*, 1891, *p.* 365 *et sequ*), in a lecture before the Medico-Psychological Association, in which he argues in support of the theory, that the central nervous system is to be regarded in the light of a static thermal centre and water-power; the mainspring o all vital actions. That the gray matter of the cerebro-spinal axis is the seat of a slow combustion while the white matter supplies the combustion material, and that this accounts for the grand nerve phenomena of life in action, and their repose in sleep both states depending on variations of tension.

It is also claimed for the theory, that it explains the effects of varying external pressures and temperatures on the central nerve-organism. The autho assigns to the cerebro-spinal fluid the most important function, holding it to be the condensed fluid o the combustion of the cerebro-spinal axis, which latter is not merely an absorbing centre for the reception of external vibrations, but a true chemical and dialysing centre and the centre of static combustion The theory looks upon the ganglia as supplementary centres supplied from the main source, while plexuses are inter-communicating points of nerves to enable vibrations to be carried on, should one or mor nerves of a plexus fail to functionate, while decussating fibres are the means by which centres are prevented from becoming independent of each other an losing their compensating balance. There are two distinct combustions in the body. The one static, in the central nervous system, the other in the muscular and active vital organs, yielding the animal heat recognized as the sensible heat of the body. The latter, while apparently independent and more active, may possibly depend for its continuous existence on the slower cerebral combustion, that keeps it alight and regulates its activity by regulating its blood supply, and through this its oxygen and combustible material.

This theory has at least the charm of being well presented, with the additional merit of attempting an explanation of nerve-function upon a purely physical and chemical, *i.e.*, scientific basis, and while indeed, like all other theories upon nerve force, it fails in unveiling this great mystery, the method adopted by its author is the only one that promises a rational solution of the question, for it is the only method to be applied in modern physiology, and to which our science owes every advance that has been made in an elucidation of the problem of life.

Beard (*Northwestern Lancet*, 1891, pp. 181, *et sequ*), after a resumè of the theories of sleep as advanced by Preyer and others, reaches the conclusion that sleep appears to be the result of a fall of temperature incident to the decline of destructive metabolism in the nerve centres, while insomnia is the result of a maintenance of a pseudo-active metabolism and of consequent temperature in these cases. The practical conclusions to be drawn from this theory are, that those remedial measures which directly diminish metabolism and thus reduce cerebral temperature best afford immediate relief from insomnia; that those agents indirectly producing this result through their influence on the vascular system, are of secondary value only, while those permanently improving nutrition, stimulating waste-removal and restoring the normal ebb and flow of metabolic activity in the nerve cells: electricity, massage, etc., have the largest field of usefulness in the cure of insomnia.

The sense of muscular effort is treated at length by Waller (*Brain*, 1891, p. 179), who sums up his views by holding that the duly coördinate action of the muscular execution depends upon three factors: the muscular coördination at the central origin of action, resulting from past experience and consisting in the emission of nerve impulses grouped and measured in conformity with intended and foreseen effects. Appropriate reflex response, of which the immediate causes are centripetal impulses from sense organs, including those from the skin, muscles, and articulations, collectively referred to as muscular sense. Direct muscular response to passive stretching and extensive vibrations.

Belmondo and Oddi, (*Arch. Ital. de Biol.*, 1891, p. 17) offer experimental researches of great interest, on the influence of the posterior spinal roots upon the excitability of the anterior roots with the following important results: 1. In destroying the conductivity of the posterior roots by means that cause no irritation whatever, there is found a constant diminution in the excitability of the corresponding anterior roots. 2. Every excitation of the sensory roots per contra, increases during a longer or shorter period, the excitability of the anterior roots. Sometimes this hyper-excitability is preceded by a period, generally very brief, during which the excitability of the anterior roots is lost or greatly diminished. 3. These different factors seem independent of cerebral influence and consequently of consciousness, at least in the proper sense of that term. This influence is not affected by section of the medulla oblongata. The authors hold, that stimuli are constantly reaching the central nervous system from the periphery and pass into the motor roots.

In this connection may be noted the investigations of Schaffer (*Arch. f. Mikrosk. Anat.*, 1891, p. 157) upon the arrangement of fibres in the spinal cord. undertaken in blind worm, grass-snake, tortoise, lizard, rabbit, bat and cat, proving that fibres from both sides of the posterior horn go directly through the anterior commissure into the opposite anterior column. Fibres also pass from the lateral columns into the opposite anterior column.

Our knowledge of the physiology of the cranial nerves has received some important additions; thus Bernheimer, in a very valuable study of the origin of the optic nerve, made upon the brain of the human fœtus, and of the new born, shows that the external corpus geniculatum is not merely a ganglion *through* which the fibres of the optic tract pass, but that it is a true place of origin for many of these fibres. That the second bundle of tractus-roots, perhaps the largest bundle of all, comes from the corpus subthalamicum. That a few fibres are derived from the internal geniculate ganglion, while two fibre-tracts can be demonstrated as coming from the thalamus opticus, viz., a deep and a superficial root. Now the importance of these researches lies in this, that they show that we have hitherto had an exaggerated idea of the significance of the corpora quadrigemina as points of origin of the optic nerve, for while the author thinks that there is a root derived from the posterior corpora quadrigemina, he appears to doubt the existence of a root derived from the anterior corpora quadrigemina. He also failed to prove the existence of the so-called descending root; of the origin from the oculo-motor nucleus and from the crus cerebelli. These results, if found correct, must modify our views upon the functions of the subthalamic bodies, optic thalamus and corpora quadrigemina as relating to vision.

Hebold (*Neurol. Centralbl.*, 1891, p. 167) concludes from pathological data, that the fibres in the optic nerve pass in closed bundles; the uncrossed bundle lies on the outer side of the optic nerve, chiasm and tract, while the crossed bundle is central in the nerve, but ventral in the tract.

The *oculo-motor* nerve is generally looked upon as the only nerve of accommodation, but Morat and Doyon (*Arch. de Physiol. norm. et pathol.*, 1891, p. 507) offer experimental proof in favor of the view, that instead of one, there are in reality two nerves of accommodation: the oculo-motor for near vision, and the sympathetic for distant vision; and that the latter acts as an inhibitory nerve to the former, hence the cervical sympathetic, carrying these fibres to the eye is the inhibitory nerve of accommodation.

In connection with the trigeminus we find an interesting point in an experiment by Gley (*Compt. rend. Soc. de Biol.*, 1891, p. 173). He presented before the Société de Biologie a rabbit, in which intracranial section of the ophthalmic division of the trigeminus, together with that of the oculo-motor, was not followed by trophic changes in the eye, although that organ was completely anæsthetic. This is additional proof against the theory that trophic lesions following sections of the V. are due to irritation of foreign bodies and loss of sensibility in the parts supplied by the nerve.

From a study of a case of bulbar paralysis and the areas of degeneration in the medulla as shown by the microscope, Tooth and Turner (*Brain*, 1891, p. 473) present some interesting and important conclusions on the cerebral origin of certain cranial nerves. These investigations support the views of Mendel, derived from experiments on rabbits, and guinea-pigs, that the oculo-facial group of muscles receives its nerve supply from the oculo-motor nucleus by way of the facial. They also show that the oro-facial group (orbicularis oris) is presumably innervated by the hypoglossal nucleus; that the motor fibres for the palate and larynx carried in the accessorius vagi are in all probability derived from the region of the hypoglossus nucleus. These results are not only of interest in point of diagnosis and pathology of bulbar paralysis, but equally interesting from a physiological point of view, as illustrating the rule, that muscles usually or habitually acting in harmony receive their motor supply from the same central source, although these fibres may in part be carried to them by different peripheral nerve tracks.

The old controversy as to the seat of origin of the auditory nerve has led Sala[1] to new experimental researches with a view of settling this mooted point, and he feels himself justified in the conclusion, that neither Deiter's nor the dorsal, nor Bechterew's nucleus have any claim to be considered points of origin of the auditory nerve, but that the anterior nucleus and the lateral tubercle are the real and only nuclei of origin, the former for the anterior, the latter for the posterior division of the nerve.

Howel and Huber[2] state that the communicating branch between the superior and inferior laryngeal nerves (Galen's anastomosis) does not carry depressor fibres from the heart, but that, as proven by experiment and secondary degeneration in the dog, it is a sensory branch of the superior laryngeal for the trachea and œsophagus, although fused with the inferior laryngeal in part of its course. This proves Longet's supposition to have been correct, who believed that the œsophagus received a sensory nerve supply from the laryngeal through this anastomosis.

Our knowledge of the function of the phrenic nerve has been increased by Ferguson (*Brain*, 1891, p. 282), who adduces conclusive proof, experimental as well as pathological, that the phrenic nerve is not, as generally held, a purely motor, but a mixed nerve, thus supporting the opinion expressed by Ross from a clinical standpoint, and the suggestion made by Peter and Henle.

The *sympathetic* system has received considerable attention at the hands of physiological investigators. Thus Arloing (*Arch. de Physiol.*, 1891, p. 160) records the continuation of his researches on the functions of the cervical sympathetic, which lead him to the conclusion that the cervical sympathetic contains trophic fibres. The experiments were made on the ox and dog. The muzzle of the former showed marked histological changes in the papillæ and stratum granulosum after section of the nerve. In the dog the changes were not immediate, because of absence of glands in the more hairy parts of its nose, which are abundant in the ox. But the changes were marked after two months, the skin of the nose becoming papillated and dry, with great hypertrophy of the corneous layer. He interprets these results by concluding that the cervical sympathetic supplies trophic fibres to the glands and epithelium, and that their action is independent of that of the vaso-motor and glandular fibres.

The same author (*Journ. de Méd. veter. et Zooteich*, 1891, p. 171), contributes researches upon the secretory functions of the cervical sympathetic as affecting the activity of the lachrymal, sebaceous and sudoriparous glands, and finds that its action is inhibitory to lachrymal secretion, but excitor to the sebaceous and sudoriparous glands.

Sherrington (*Brit. Med. Journ.*, 1891, p. 635) finds that the excitation of the cervical sympathetic in the monkey by feeble induction shocks thrown into the peripheral end of the divided nerve of one side (the animal being under an anæsthetic), results in a slight enlargement of the palpebral aperture by a lifting of the upper lid, dilatation of the pupil, a drawing back of the pinna of the ear, with slow erection of the skin of the nostril and hair of forehead, temple, cheek and upper part of whiskers, giving an expression of surprise and fright. Section leading to the converse, with slight flushing of the upper gum. As, according to Dr. Hall White, the collateral ganglia of the sympathetic are atrophied and degenerate organs like the coccyx and appendix cæci, the question suggests itself, whether loss of hair from the front of the human scalp, the common form of baldness, is not a phenomenon due perhaps to degeneration of the superior cervical ganglion in man, contended for by White.

As to the action of *pilo-motor* nerves, Langley and Sherrington state (*Journ. of Physiol.*, 1891, p. 278) that the hairs of the monkey, cat, and probably all animals in which horripilation takes place under the influence of strong emotion, may be erected by stimulation of nerve fibres coming from the spinal cord and passing through the sympathetic system. The effects are mainly unilateral, but bilateral in the tail.

Langendorf (*Centralb. f. Physiol.*, 1891, p. 129) confirms the researches of Langley and Dickinson showing that the fibres of the sympathetic chain do not simply pass through the ganglia intercalated in their course, but end there, in order, so to speak, to be, regenerated and to issue from them in a new state. Dastre (Compt. rend. Soc. de Biol.) comments on Langendorf's experiments, and claims that his researches on the same point and leading to similar conclusions were made in 1879–1884, and that the authors mentioned only confirmed his conclusions. That he, however, went beyond them and reached the general conclusion that the ganglia of the sympathetic chain are tonic and inhibitory centres. He holds that the vaso-constrictor nerves issue from them, while the vaso-dilators end *in them*, and claims analogous functional activity for the minute peripheral ganglia disseminated in the various organs.

Any consideration of the functions of the sympathetic system, at once brings forward the vexed question of *trophic nerves*, which finds an able treatment at the hands of Arndt (*Arch. f. Anat. und Physiol.*, 1891, p. 54 *et seq.*) in an exhaustive consideration of the subject from all points of view. The author holds that the existence of trophic nerves is beyond all doubt, and in support of this adduces experimental and clinical evidence. The latter, collated from a wide range of pathological observation, includes among many others, cases of paralysis with decubitus; surgical section of nerves with decubitus, lesions of the brain-stem followed by ulceration and perforation of the stomach and small intestine; jaundice after strong emotions, ascribed to trophic processes in the liver; desquamative nephritis from emotions; zoster, herpes, urticaria, due to trophic nerve influences. He holds that there must be trophic nerves, that this is proven by the numerous observations of Virchow, Nasse, Nélaton, Cl. Bernard, Légros, Onimus, Schiff, Joseph, Heidenhain and many others. Now, the question is, where are these nerves to be looked for, and how can we find them? As yet they have only been demonstrated directly on the corneal cells (Kühne), the pigment cells of amphibia and reptiles (Ehrmann), and on the cells enclosing the stomata of lymph spaces (Hoffmann), while their presence elsewhere has been assumed from physiological, but more especially from pathological data. They have been postulated, but also quite as frequently rejected, because not visibly demonstrated. This failure of demonstration is due to the fact that we had no clear idea as to what was to be looked for; and because we failed to recognize in its true character something we had long possessed, viz.: trophic nerves, that may be demonstrated at all times. To support this dictum, the author refers to his studies in 1890, proving that the nerves and the entire nervous system, developed as they are, from the ecto- and entoderm, represent a reflex rather than an automatic apparatus. Thus a given nerve is excited, *i.e.*, some process of movement passes along it and calls forth a corresponding movement. This movement passes from the place where it originated, to the end-cells supplied by the nerve, as is shown by production of heat, electricity, etc. The first thing, therefore, that is excited, or inhibited or destroyed by nerve action is metabolism, and as all the phenomena of nutrition depend upon this, it follows that the trophic processes must be influenced by any nerve excitation. Thus every nerve, and especially every centrifugal nerve, is primarily a trophic nerve, which, exciting trophic processes, leads secondarily to secretion, contraction, motion, usually supposed to be produced directly. These visible results are in reality only the outcome of trophic processes produced by the nerve. Afferent nerves act in a manner analogous to efferent nerves, by regulating the vital processes in the cells of the central nervous system, and the phenomena of sensation, consciousness, volition, etc., are the secondary but not the primary results of the impulses reaching the central cells by way of centripetal nerve fibres. Hence, according to the author, there is no necessity whatever to assume the existence of special trophic nerves, nor to ascribe trophic action to the sympathetic, when no other trophic nerves can be demonstrated. The sympathetic as a matter of course regulates the nutritive supply by its action on the vascular system, but it is trophic in the strict sense, only or especially for the smooth muscles supplied by it. Every nerve being trophic, should we retain the terms sensory, motor or secretory to designate the functional differences of nerves? For the sake of convenience, why not? But no nerve *per se* is either sensory, motor or secretory; it only causes sensation, motion or secretion by exciting its end-cell. It would therefore be better to speak of nerves as *centripetal and centrifugal*; or still better, to classify them as receptive and reactive; for upon reception of excitation and reaction thereto, brought about by chemico-physical processes, comprised under the more concise term of nutritive processes, all life is based, and this life finally is only a chemico-physical process, composed of what we briefly call assimilation, and in a wider sense of the term, secretion.

---

[1] Monitore Zoologico Italiano.

[2] Jour. of Physiol. 1891, p. 5.

As the existence of special trophic nerves has been the favorite bone of contention among physiologists, while pathologists and clinicians appear long since to have reached an agreement from clinical phenomena, Arndt, in taking the broad ground that all nerves are trophic in the proper sense of the term, and that the evidences of their action as expressed in sensation, motion, secretion, etc., are but the secondary, the necessary outcome of their primary trophic function, propounds a theory that seems to embrace the greatest number of facts in a very satisfactory manner. As a "working theory" it appeals alike to the physiologist and the clinician, and offers a rational explanation of experimental as well as pathological phenomena, until now ascribed to the action or non-action of specifically trophic nerves. It certainly is a great and important step in the direction of removing this *quæstio vexato* of *trophic* nerves from the arena of physiological controversy.

The important field of reflexes has received some very valuable additions, representing perhaps the most positive gains made during the year, and certain to prove of great service in the diagnosis of a number of diseases of the nervous system.

Hughes (*Alienist and Neurol.*, 1891, p. 44) calls attention to a reflex (Onanoff's bulbo-cavernous reflex) possessing great physiological and pathological significance, because active in all healthy male adults with normal spinal cords, but absent in infants, feeble or absent in males before puberty. It is impaired by excessive venery, by masturbation, lowered in the later stages of typhoid fever. This reflex he calls the virile reflex, or penis percussion reflex. Its presence or absence is a valuable sign of the vigor, impairment, loss or abeyance of sexual power in the male. In a paper read before the Section of Medical Jurisprudence (Journ. Am. Med. Assoc., xvii, p. 727) he adds clinical evidence proving the value and significance of this reflex in diagnosis.

Jacoby (*New Yorker Med. Monatschr.*, 1891, p. 363) describes a new and interesting reflex phenomenon, produced by applying the galvanic current to the dorsal part of the hand and wrist. It consists in a short lightning-like contraction of the levator menti, when the current is closed; the contraction sometimes extends to the quadratus (both supplied by the facial nerve). In strongly marked cases, when both forearms are excited simultaneously by cathode, there is elevation of the chin, and the middle of the lip is protruded, giving to the face an expression of haughtiness or contempt.

Another addition to our knowledge of reflexes is made by Lazarus (*Arch. f. Anat. und Physiol.*, 1891, p. 19), who shows experimentally, that a reflex may be produced from the nasal mucosa to the bronchi; that certain irritants applied to the former reflexly cause a diminution of the lumen of the bronchi; and that the centrifugal part of this reflex is to be found in the vagus; also that it is more than probable, almost certain, that this lessening of the lumen is due to contraction of the bronchial muscles. Zuntz, in speaking of this reflex, points to its bearing on the respiratory process. He says, it might seem that the greatest possible width of the bronchi would be most advantageous for respiration, and that in fact, contraction of the bronchi cannot be favorable to the filling and emptying of the lungs, but it possesses an essential significance in that it frees the air from all dust particles before it reaches the alveoli. The task to free the respired air from dust will be the more difficult, the greater the amount of dust contained in it. Hence a contraction of the bronchi becomes of importance, when the respiratory air is thus contaminated. This, indeed, renders respiration more difficult, but at the same time insures pure air to the alveoli. At the hand of these experiments, we can readily understand why in a pure air, free from particles of dust, we can so readily expand the chest, and why, *per contra*, when the respired air excites the nasal mucosa by dust, by its temperature, or by carrying irritant gases, the phenomena of labored respiration make their appearance.

A new reflex, *the anal*, is described by Rossolimo (*Neurol. Centralbl.*, 1891, 257). After speaking of the segmentary arrangement of reflex function of the spinal cord and its great importance in the localization of diseases of the cord, he deems a study of a new reflex segment not superfluous on anatomical, physiological and clinical grounds. The phenomenon in question occurs upon every contact with the integument and mucosa of the anus, and is accompanied by contraction of the sphincter ani, found in all normal men without exception. The integument of the anus and its mucosa as well as the sphincter ani externus are innervated by the external hæmorrhoidal nerve, formed from the third and fourth root of the sacral plexus. Hence, we may, upon these facts assume that the center of the anal reflex is near the third and fourth sacral roots, *i. e.*, in the lower conus medullas. In the dog it is located in that part of the cord corresponding to the third sacral root, *i. e.*, in the third fourth, counting from above, of the lumbar enlargement. The reflex arc is composed of the fourth sacral nerve and the centre, which in the cord lies above the root of the fourth, near the third pair of sacral nerves. It is thus placed below all other skin reflexes, even below the plantar reflex. It is pathologically increased: in neurasthenia, with increase of all skin reflexes, in high transverse myelitis, in anatomical disease of the nervous system with increased function of the sensory apparatus. It is decreased or destroyed in multiple neuritis with extension of the process to the sacral plexus; in cases of tabes, where there is disease of the pelvic organs and a more or less pronounced anæsthesia of the anal region; in myelitis of the lower segment of the lumbar enlargement. It remains normal in functional neuroses of micturition, defecation and sexual power. A knowledge of this reflex thus facilitates on the one hand the differential diagnosis of functional and organic disturbances of the pelvic viscera, and on the other a more accurate localization of the pathological processes in the spinal cord.

A curious form of what he calls inhibition, is described by Brown-Séquard (*Arch. de Physiol. norm. et pathol.*, 1891, p. 507). He thinks that surgeons might avail themselves of it, should the same condiions obtain in man, as found experimentally in the ape and dog. His experiments on these animals show that wounds produced by cutting or burning, may, after excitation of the larynx or its sensory nerves, become analgesic, and remain in that condition for several days, and even two weeks or more. He finds that wounds inflicted either before, during or a short time after certain irritations of the laryngeal mucosa or its sensory nerves, always present a total loss, or else a greater or less diminution of sensibility to painful impression.

The same author (*loco. citat.*, p. 805) supplements the foregoing by experimental evidence showing that in the ape and dog, a general reflex analgesia may be produced by a traumatic or mechanical irritation of the integument of the neck, the trachea, and especially of the larynx or the superior laryngeal nerves, and also by irritation of the laryngeal mucosa by chloroform, cocaine, etc. Should these results be verified in man, surgeons would be placed in possession of a ready and safe method for the production of local analgesia.

Wedensky (*Compt. rend. Acad. des Sciences*, 1891, p. 805), from a series of experiments undertaken with a view to solve the question in which part of the neuro-muscular apparatus inhibition is produced, is led to the conclusion, that the peripheral nerve endings, and not the muscular fibres pass into a state of inhibition, when frequent and strong excitations are applied to the neuro-muscular apparatus.

The physiology of the medulla oblongata has received attention at the hands of Spencer (*Proc. Royal Soc.*) whose researches were for the purpose of connecting more closely clinical signs with pathological changes in the medulla oblongata by localizing in the floor of the fourth ventricle the centers influencing respiration and circulation. He finds that the *respiratory* center lies along the middle line, extending for 2 mm. on either side, while that for *expiration* lies along the lateral part of the ventricle 2 to 3 mm. from the middle line. Upon the other hand, respiratory rhythm is slowed by excitation of an area lying over the continuation of the postero-median column, as the latter separates from its fellow on the opposite side, and that part of the floor of the ventricle close to the inner border of the column. Its central part is between 1 and 2 mm. from the column and between 2 and 3 mm. from the middle line.

Cardio-inhibition, although it may be produced all over the floor of the fourth ventricle, and also in rear of the calamus, is best marked over the posterior third of the ventricle, and over the inner margin of the continuation forward of the postero-median column. The chief depressor center is located in the hinder part of the floor between 1 and 4 mm. in front of the calamus, while rise of blood pressure is most frequent upon excitation of the floor from 4 mm. in front of the calamus to the anterior border of the ventricle.

The question of the existence or non-existence of a special center for vomiting, a long disputed point in the physiology of the spinal axis, appears at last to have been successfully solved by Thomas (*Arch. f. path. Anat.*, 1891, p. 49). At any rate, the experiments seem to leave no room for doubt that such a center exists in the dog and cat. He demonstrates that there is an independent vomiting center, as held by Mayer; that this central apparatus occupies a space 5 mm. long by 2 mm. wide, lying in front and rear of the calamus scriptorrius and within the deeper parts of the medulla oblongata. It is functionally and anatomically independent, and represents a mechanism of a higher order connected with numerous other centers of a subordinate character, and capable through excitation of the latter, to produce its characteristic end effects. This, if correct, removes the question of a vomiting center from the region of controversy and hypothesis, where in spite of numerous investigations, it has remained heretofore, and thus marks a distinct advance in our knowledge of the functions of the medulla oblongata. It also disposes of Hlasko's theory (*Inaug. Dissert, Dorpat*), that the corpora quadrigemina are the centers from which the impulses causing contraction of the cardia proceed by way of the vagi and cord.

Ott (*Jour. of Nerv. and Ment. Dis.*) adds to our very meagre knowledge of the functions of the thalamus opticus, some experimental data pointing to its vasomotor influence, since section immediately in front of the pons, causes a fall of tension in the blood vessels. He thinks it quite probable that certain peripheral nerves stand in reflex relation to vasotonic centers in the thalami, which latter exert a vasotonic action upon the medullary dominant vasomotor center. These experiments throw some light on the obscure relations of the base of the brain to the chief vaso-motor center.

As to brain physiology, some important observations must be noted. Danilewsky (*Centralbl. f. Physiol.*, 1891, p. 1–4) adds to our knowledge of the electro-motor processes in the cerebrum, experimental evidence, proving that the conditions of excitation produced there by external irritants, are accompanied by definite electro-motor phenomena, the latter being regarded as objective signs of psychical processes, that subjectively appear as sensations, motions, hallucinations, etc. Thus, even feeble stimulation of a sense organ or of the internal sensory nerve (the vagus) produces an evident change in the electro-motor conditions of a definite region of the cortex, usually on the opposite side, which is set aside by deep morphia or chloroform narcosis. The *electro-motor* method of investigation is of value, not only in the question cerebral localization, but also in the investigation of the processes of excitation as such in the cerebral cortex.

Ireland (*Brit. Med. Jour.*, 1891, p. 1167) discusses the discordant action of the double brain, and shows that, one hemisphere remaining healthy, the other being diseased, the integrity of the intellectual, moral and emotional faculties may be preserved, and perhaps better preserved with a total destruction of one hemisphere, than with a diseased hemisphere transmitting irritation to its fellow.

Some interesting points on the cerebral circulation have been brought out by de Boeck and Verhoogen (*Institut. Solvay*) by studying some of the conditions under which it may be altered. They reach the following highly practical conclusions: In asphyxia the amount of blood in the brain is increased throughout, not because of increase of general blood-pressure, but from active dilatation of the cerebral vessels. Injection of sulphuric ether produces increase of arterial blood pressure, leading to a more abundant blood supply, while intravenous injection of morphia does not alter the total amount of blood in the brain, but changes the manner of its distribution, inasmuch as the cortex becomes anæmic, while the base is rendered hyperæmic.

Cybulsky (*Centralbl. f. Physiol.*, 1891, p. 834) holds that v. Bergmann's investigations on brain pressure and his theory thereon, afford a sufficient explanation of the subject, fully corresponding to clinical observation. Surgeons must be surprised to learn that Adamkiewicz looks upon brain pressure as impossible, even asserting that when local pressure is produced by inserting pieces of laminaria into the cranial cavity, there results, not anæmia, but hyperæmia. Cybulsky's investigations lead him to conclude that intra-cranial pressure is always positive, presenting considerable variations due to the state of the cerebral circulation. In dogs the variation is between 72 mm. to 190 mm. H_2O. Intra-cranial pressure, *i. e.*, pressure of the cerebro-spinal fluid, may be greatly increased by diminishing the cranial space by foreign bodies, *e. g.* a hæmorrhage from an artery outside of the dura mater. If under a certain degree of blood pressure, a 0.6 per cent. solution of sodium chloride, or oil be introduced beneath the dura, or if they, or an india-rubber bladder be forced between dura and bone, we see, when pressure is equal to that of the blood in the carotids, the symptoms of increased brain pressure, slow pulse, increased arterial pressure, acceleration, followed by slowing and finally cessation of respiration, loss of consciousness and death, with coma and tetanus. The rapidity of flow in the internal carotids is decreased as soon as intra-cranial pressure is increased; and again accelerated when with the same intracranial pressure, general blood pressure is increased. Whenever intra-cranial pressure becomes higher than the arterial, there is cessation of the cerebral circulation. These changes in the rapidity of the flow show that increased intra-cranial pressure leads to brain anæmia, and the symptoms *mentioned are the results of this* anæmia. (This fully agrees with v. Bergmann.) Injection of neutral or ammoniacal salt solution into the cerebral vessels does not produce these results. (This contradicts Adamkiewicz). He produced local pressure in rabbits by placing pieces of laminaria within the skull, and is convinced that this depression of brain substance is connected with displacement and disfiguration of the brain, and also with pressure on the blood vessels and ventricles. Such pressure remains latent only, when the volume of laminaria introduced does not exceed $\frac{1}{19}$ to $\frac{1}{20}$ of the volume of brain. If greater, there are changes in the circulation, numerous extravasations, producing death sooner or later. Adamkiewicz' assertion that the skull space may be decreased by $\frac{1}{6}$ or $\frac{1}{4}$, without production of death, depends as he thinks, on erroneous measurements.

That essentially modern offspring of our science, dating its birth from the discoveries of Fritsch and Hitzig (1870), and truly inaugurating a new era in the physiology and pathology of the brain, viz.: the doctrine of cerebral localization, or if you please, "scientific phrenology," *has not fallen behind* in the general advance of nerve physiology. Its importance *per se*, as a new physiological doctrine, and the brilliant results of its application in brain surgery, have made its study not only of great inherent interest, but of the highest practical value. While indeed, accepted by the majority of physiologists, it still finds able opponents in our ranks, and the literature of the past year shows that it yet lacks the seal of unanimous approval.

Perhaps the most important work on localization published during the year is presented by Gotch and Horsly (*Philosoph. Trans.*, 1892, p. 269–526) being a magnificent monograph entitled "The Mammalian Nervous System, its Functions and their Localization Determined by an Electrical Method." It is the substance of the Croonian lecture, and after a full description of the method and plan pursued by the authors, it gives a full account of the important results of their investigations. It is impossible, within the limits of this paper, to do even scant justice to such a work by attempting to summarize its contents. It can only be fully appreciated by careful study, which, however, will fully repay for the time and labor employed by imparting information absolutely essential to a clear understanding of modern nerve physiology and its methods.

Beevor and Horsley (*Philos. Trans.*, 1891) in another finely illustrated monograph, give an extensive account of their experimental investigation of the motor paths in the internal capsule of the dog's brain. They show that the arrangement of the motor fibre corresponds exactly to the arrangement of the motor areas in the cortex. They also disprove that the trunk muscles, and those of the tongue of each side possess bilateral innervation, as heretofore supposed.

Donaldson (*Am. Jour. of Psych.*, 1891, p. 113) publishes an abstract of six lectures on cerebral localization, aiming especially to show the bearing of recent anatomical investigations on this point. After a description of Golgi's method of investigation of nerve structures, he gives a resumé of the advances in our knowledge of nerve cells and fibres and their mutual relation, presenting an excellent picture of the architecture of the cerebral nervous system. He next considers motor and sensory localization in man and ape, and discusses the results of experiments in animals lower in the scale, concluding with a consideration of the connection between localization and psychology.

These lectures form a valuable addendum to physiological literature, and the author deserves our thanks for the clear and concise presentation of the question in all its bearings.

Santmeyer (*Zeitsch. f. Biolog.*, 1891, p. 177) adds to our knowledge of conduction paths, by a description of the secondary degeneration following extirpation of motor centers in the dog. He finds that unilateral extirpation of motor centers frequently, but not always, leads to bilateral degeneration, and that the degeneration on the side of the lesion may occur as early as that in the opposite tracts. The degeneration on the same side has not as yet received a satisfactory explanation. The degenerated fibres appearing in the later stages in the anterior and posterior column, are not in direct connection with the extirpated centers. There are no anterior pyramidal tracts in the dog. The lemniscus, the nuclei of Goll's and Burdach's columns, the anterior spinal roots and the peripheral nerves are not attacked by secondary degeneration.

Bernheim (*Rév. Méd. de l ést.*, 1891, p. 513) illustrates motor localization in the cerebral cortex by a case of left brachio-facial monoplegia, followed by an attack of apoplexy with right hemiplegia. History and autopsy confirm the localization of motor centers in man as given by Charcot and Pitres. Brachio-facial monoplegia coincides with lesion of the inferior half of the ascending frontal convolution. 2. Sacral and lingual monoplegia depends on lesion of the inferior extremity of the motor zone, especially of the ascending frontal. 3. Brachial monoplegia on a limited lesion of the middle motor zone, especially of the ascending frontal. 4. Crural monoplegia on a very limited lesion of the paracentral lobule.

Shaw (*Brit. Med. Jour.*, 1891, p. 946) had the somewhat rare opportunity of examining the brain in a case of an old amputation of the thigh, and found atrophy of the cerebral cortex in the region corresponding to the leg center, with absence of the giant pyamidal cells of Betz from the ganglionic layer of the atrophied region.

While it is generally held that the auditory center is located in the first, or in the first and second temporal convolution, a view, however, not accepted by all, the report of a case bearing upon this point by Mills (*Brain*, 1891, p. 465) with history and autopsy becomes of great value. His conclusions from a study of the case are, that the center for word hearing is situated in the posterior thirds of the first and second temporal gyri, just in front of, or in a line with the posterior extremity of the horizontal branch of the Sylvian fissure. A lesion, confined to this region of the left hemisphere, produces complete, or almost complete word deafness. The field for all auditory memories is much larger, including at least, the posterior two-thirds of the first and second temporal. While these centers are most highly developed in the left hemisphere, destruction of the centers of both sides is necessary to produce complete brain deafness. The other temporal convolutions are not concerned in central audition. A lesion limited to the center for word hearing, causing word deafness, also causes paraphasia and paralexia, but it does not necessarily cause inability to recall words by other means, for instance, through their visual signs; in such cases probably the meaning of the word is understood, although the name cannot be properly verified in consciousness. Lesions causing word deafness will eventually lead to secondary atrophy of the speech and oro-lingual centers on the motor side of the brain, and to atrophy of the association tracts between the sensory and motor hearing-speech centers. The retro-insular convolutions are closely related with subdivisions of the first temporal gyrus, the most posterior being continuous with the posterior two-thirds of the first temporal gyrus.

The existence and localization of *cerebral* heat centers, first demonstrated by Landois and Eulenburg, has led to renewed investigations, notably so by White and Ott. White (*Jour. of Physiol.*, 1891, p. 271) discussing the position and value of those lesions of the brain, causing rise of temperature, states that after injury to the optic thalamus, produced by a blunt probe, the rise of temperature is slight as compared with that of a similar injury to the corpus striatum, while injury to the septum pellucidum causes a marked rise. Injury to the cerebellum produces no rise, while injury to the posterior part of the cerebral cortex has an effect more marked than injury to the frontal portion. There is a marked rise from injury to the crus cerebri.

Ott (*Journ. of Nerv. and Mental Diseases*,, 1891, p. 483) finds that the tuber cinereum is the centre for polypnœa and thermotaxis, and on the basis of his own researches revises the function of the thermotaxic centres as follows: In the fore-brain, the cortex contains thermo-inhibitory centres at the sulcus cruciatus and the Sylvian fissure. Thermogenic centres are found at the base in the caudate nucleus, the gray matter of the septum lucidum, and the gray matter in front and beneath the caudate nucleus. The interbrain contains thermolytic, polypnœic and vaso-motor centers in the tuber cinereum; the afterbrain: thermolytic, respiratory and vaso-motor centres; the spinal cord: thermolytic, sudorific and thermogenic centres.

The localization of sensory centres is still a subject upon which opinions are widely apart, as may readily be seen by the following:

Saville (*Brain*, 1891, p. 270) concludes from a highly interesting case of anæsthesia with trophic changes in which the lesion was found to be strictly localized, as shown by the autopsy, being precisely beneath those parts of the cortex corresponding to the gyrus fornicatus and part of the marginal convolution, in their entire extent, and beneath the anterior half of the præcuneus; cutting off all direct communication between the gyrus fornicatus and the white matter beneath, and in front between the gyrus fornicatus and the marginal convolution and centrum ovale, that the gyrus fornicatus is the centre for common and tactile sensations, and that its destruction may produce loss of sensation without loss of motion to any serious extent. (This case, therefore, is in line with the conclusions arrived at by Horsley and Schäfer.) He also concludes, that a destructive lesion in that portion leads to vaso-motor or trophic changes in the skin and subcutaneous tissues of the opposite side of the body, and that therefore these convolutions may possibly be the centre, not only for sensation, but for trophic influences transmitted to the opposite side of the body.

Per contra Knapp (*Boston Med. and Surg. Journal*, 1891, p. 430) presents the details of a case, tending to show that the centres for sensation of touch, pressure, motion and position are to be looked for in the central convolutions. The lesion involved the middle third of the left ascending parietal convolution. Sensations of pain and of temperature were not abolished. The limbic lobe was not involved in this case, as it presented no signs of inflammation. These results accord singularly with those of Munk's experiments, although Knapp does not fully accept Munk's opinion, that the cerebral cortical region is purely sensory.

Schtscherbach (*Centralbl. f. Physiol.*, 1891, p. 289) attempts to solve the difficult question of localization of the centre of taste in the rabbit, and finds that injury to an area extending from 2 to 3 mm. in front and behind the line of the coronal suture and vertically from the longitudinal fissure to the lower edge of the brain, causes loss of *taste* in the opposite side of the tongue, lasting for six days at most.

As opposed to the doctrine of localization, we find Lane (*Am. Journ. of Insanity*, 1891, p. 50), who holds, speaking of the so-called motor area of the cortex, that the theory of cerebral localization is not supported by sufficient evidence, and therefore concludes that, upon the facts presented, it is simpler and more consistent, therefore wiser, to consider the cortex (so far as explored) as an entirely sensory region, the seat of memory and will.

While Bennett (*Dubl. Journ. Med. Sci.*, 1891, p. 337) records the history of a case of cerebral tumor, illustrating the difficulties of cerebral localization. The tumor had destroyed the centres of volition governing the left arm and also those of other parts of the left side of the body, obliterating the lower two-thirds of the fissure of Rolando, and involving nearly all of the lower half of the ascending parietal; nearly the entire ascending frontal convolution was lost in the tumor, yet never during life was there any paralysis of the limbs. He asks, how are such facts to be reconciled with the present views of cerebral localization?

We finally must consider what has been done in advancing the physiology of the cerebellum, that fruitful field for speculation, to which numerous hypotheses have assigned at some time or other the *rôle* of being the seat of nearly every functional manifestation of the central nervous system, and which even now, in spite of its ready accessibility, of countless experiments, of an immense amount of clinical observation, and of the fact that some of our most skilled and assiduous investigators have made it their special object of research, is an organ whose physiological significance is enveloped by doubt and uncertainty. For we must confess that we have gained but little positive knowledge since the brilliant experiments of Flourens opened up the question of cerebellar function, and pointed to its connection with the motor apparatus. Whether the latest contributions have brought us much nearer to a solution of this perplexing question may perhaps, and not without reason, be doubted, nevertheless the two most striking and exhaustive monographs dealing with the physiology of the central nervous system published during the year, and presently to be considered somewhat in detail, aim to offer a solution of the question of cerebellar function as a whole, and their authors endeavor to establish theories, which although widely apart, are well presented, clearly formulated and supported by ingenious arguments, that may or may not be deemed convincing or acceptable to physiologists. Before touching upon these, however, it will not be amiss to make brief mention of a few of the experimental data on cerebellar function, that have been published during the year. Thus:

Borgherini (*Neurolog. Centralbl.*, 1891, p. 649) describes a novel phenomenon, consisting in a sleep-like state induced in dogs after removal of the cerebellum, by bandaging the eyes with a thick cloth. In this condition the animal does not respond to any mechanical or tactile excitation. The author believes that the absence of visual impressions produced by the bandage causes in the animal a consciousness of complete inability to move, and forces it into absolute immobility; it has lost the will to move.

Lange (*Pflüger's Arch.*, 1891, p. 615) shows experimentally that the symptoms due to ablation of the cerebellum must be strictly separated from those after destruction of the semicircular canals, thus opposing the views of Baginsky, who regards the auditory symptoms in the light of brain disturbances, and of Loeb, who has lately again supported the older view, that the cerebellar symptoms may be referred altogether or in greater part to lesion of the auditory nerve.

We now pass to a consideration of the two monographs that represent the most noteworthy additions to the literature on the cerebellum and its functions which have made their appearance for several years past. The first of these, by Luciani, is a volume of some 300 pages, entitled "Il Cerveletto," of which

Pescarolo (*Arch. Ital. de Biol.*, xvi, p. 289) gives a very full and clear abstract. The author presents a series of new experimental studies on the normal and pathological physiology of the cerebellum, with new facts that, according to Luciani, demonstrate the error of the doctrines now held, and tending to assist the physiologist and clinician in the interpretation of certain phenomena. The fundamental fact derived from these researches and from the best clinical and experimental observations is, that absence of a more or less extensive or deep portion of the cerebellum, or its total absence even, is not followed by any paralysis, partial or total, of either sensation or motion, or by disturbance of the intellect or volition. This leads him to look on the cerebellum, with all its dependencies, as a small system, possessing a comparative autonomy, and to a certain point, distinct from the great cerebro-spinal system. It is not an intermediate organ, intercalated along the great tract of cerebrô-spinal transmission, but rather an appendicular organ, which, by means of different afferent routes, is directly or indirectly *en rapport* with the peripheral sense-organs, and by special efferent routes has a direct connection with certain collections of gray matter of the cerebro-spinal axis, and indirect connection with the peripheral apparatus of voluntary movements. It, like the rest of the cerebral nervous system, is an organ with bilateral action, but mostly direct, unlike the mainly crossed action of the cerebral hemispheres. Its influence is not limited to the muscles of station and locomotion, but extends to all voluntary muscles, though not in the same degree, its action being more pronounced on the muscles of the lower limbs and those fixing the spine. The cerebellum is an homogeneous organ as to function; *i.e.*, every segment has the function of the whole, and in absence of the rest may supplement them, provided the normal relations to the afferent or efferent tracts be not altered.

As absence of the cerebellum, whether in animals or man, is not followed by paralysis, or imperfection or lowering of the external or internal sense, it is believed that it does not possess sensory function; still, considering the inherent imperfection in the methods employed to examine the different sensations in animals, and the difficulties of the subjective examination of the sick, because of the ready *suggestionabilité* of the subjects, the author abstains from pronouncing on this question, and leaves it to future investigations. The grand total of results shows, that ablation of the cerebellum is always followed by neuro-muscular phenomena of an asthenic, atonic and astatic character, hence the influence of this organ upon the rest of the system is complex in character, procuring, 1, an increase of potential energy at the disposal of the neuro-muscular apparatus (sthenic action); 2, an increase of their tension during functional pauses (tonic action); 3, an increase of the rhythm of elementary impulses during action, with a normal fusion and regular continuity of the act (static action). And as every functional excitation of living elements is necessarily accompanied by a modification of nutritive movements it follows, that the complex action of the cerebellum is connected with a trophic action directly or indirectly. This trophic influence is naturally slow, tranquil, continuous, yet varied in intensity in the normal condition of the organism, and the functional influence of the cerebellum, normally exerted upon the other nerve centres, is likewise slow and continuous. The activity of the cerebellum is not specific, or *sui generis*; it is the common, fundamental activity of the entire nervous system.

The peripheral nerve ganglia of the sympathetic system, possess fundamentally an analogous relationship to the functions of vegetative life, as demonstrated by Luciani's researches on the functions of the ganglia of the posterior roots, which are claimed to have shown, that, like the cerebellum they possess a trophic action and also the function of reinforcement, both to be considered as different manifestation of the same process, that constitutes the unexplored and as yet mysterious field not only of the physiology of the cerebellum and of the intervertebral ganglia, but of that of the nervous system in general.

The other work referred to, differs from the foregoing, being of a decidedly revolutionary character, as the views expressed by its author are opposed to all that is held to be almost axiomatic in cerebellar physiology, the doctrine, that this organ does not take part in the mental processes. This volume of some 600 pages is by Courmont, and bears the title: "Le Cervelet et ses Functions, Paris, 1891." It received what may be called a preliminary review at the hands of Prof. Forel (*Bull. Med. du Nord.*, 1891, p. 244), from whose article the following synopsis has been obtained. According to Ford, the author, one day, while sitting at the bedside of a patient, was seized by an original and bold idea of cerebral physiology, which he formulated into an hypothesis of the functions of the cerebellum, according to which the latter is an organ *de sensibilité* and endowed with psychical functions. To verify this hypothesis, and judging that vivisection (although direct experiment was not neglected) because of the mutilations attending it, supplied less clear results in questions of cerebral localization, than those obtained from a study of clinical facts followed by autopsy; he searched, to use Forel's words, with the patience worthy of a benedictine monk (some might say, worthy of a better cause) through all the original French and foreign observations on cerebellar disease, and was astonished to find that they all confirmed his *á priori* conclusion. Again certain anatomical considerations, and experiments conceived in quite a different spirit and conducted with another end in view, equally supported the hypothesis. Comparative anatomy also supplied serious arguments in favor, and finally direct experiments brought all the confirmation they could offer to the author. Now, since the time of Flourens, the functions of the cerebellum are held to be those of coördination, but the author says, if setting aside all prejudice established by science, some one should propound to a physiologist the following: Given, an important encephalic organ, nearly identical in structure with the cerebrum, and not only placed alongside of but associated with it by close and intimate anatomical connections, should not such an organ possess functions analogous to those of the cerebrum? Clearly, the answer would be: *Yes.*

Now, the cerebrum is a motor organ, and at the same time that of thought, and Courmont holds, that the cerebellum also is the general receptacle for sensations and presides over a special class of psychic manifestations. Dividing the faculties into rational and emotional, he holds that reason, judgment, volition, etc., belong to the cerebrum, while the emotions, love, fear, hatred, etc., have their seat in the cerebellum. (Jessen of Erfurt, formulated this idea in 1869, but advanced no proof in its support.) Courmont adduces in proof arguments from anatomy, based on analogy and held to establish a probability only; thus the cerebrum and cerebellum are each composed of two hemispheres, each contains a central white, and a peripheral gray substance. In both, the nerve fibres arise from nerve cells and form peduncles passing to the spinal cord. True, the cerebellum is much smaller but its gray substance is more abundant than the white. The comparative weight of the cerebellum is less in the male than the female, and in the latter the emotions predominate. Finally the motor columns of the cord pass to the cerebrum, the sensory to the cerebellum. And Kölliker is cited as holding that the anatomical disposition of the cerebellum illy accords with the theories of its motor functions. As to experiment, Vulpian and Ferrier are cited, to prove that animals deprived of the cerebellum still experience pain and give signs of emotion. But clinical observations with autopsies supply the main foundation of the new idea, as a like observation first gave birth to it, and as this case shows more clearly the author's method of reaching conclusions, it may properly be briefly reproduced: A woman with puerperal mania presented a singular condition. She responded sensibly and rationally to all questions bearing on external facts, but at once became delirious when a word was pronounced, that set her emotional faculties into play. Now, rejecting the idea of two different classes of cells in the cerebrum, because the circulatory disturbance presumably producing the puerperal mania, could not affect one class, without at the same time acting upon the other, our author concludes, that there must be two organs, one presiding over reason, the other over emotion, and in his further search he finds divers psychical symptoms in cases of cerebellar lesion, such as changes of character, inexplicable irascibility, sadness without external cause, etc., claimed in support of the theory. As to experiment, he finds that ablation of the cerebellum in rats is followed by apathy, while its complete removal, producing inflammation of the remainder exaggerates the emotional conditions. The comparative and absolute highest development of the cerebellum in man is also held as proof in his favor. Other considerations are brought to bear; thus in examining the origins of the cranial nerves, he finds that those coming in part or altogether from the cerebellum, cerebro-peduncles or tubers, are the ones most affected in the emotions: the lachrymal, patheticus, facial, auditory. The anatomical disposition of the last affords an original explanation of the fact, that music, of all the arts, has the highest power to move man by means altogether exclusive of reason. Finally, the cerebellum, like the cerebrum, receives sensory impressions, as shown by the origin of the auditory nerve, the trigeminus, the posterior columns of the cord.

The psychical and sensory theory of the cerebellum admitted, our conception of the cerebral nervous system is according to Courmont, greatly simplified according to the following plan: there are two grand divisions, the spinal cord and the encephalon. Each is composed of two parts: the cerebrum and the anterior spinal cord are motor, the cerebellum and the posterior cord sensory, and upon these functions the two psychic functions, volition and emotion are based.

The motor disturbances from lesions of the cerebellum are explained by the supposition, that the posterior encephalon acts by a reflex mechanism upon the anterior encephalon, an action analogous to that of the posterior cord on the anterior; hence we see incoördination from experimental lesions of the cerebellum, and uncertainty of gait in cerebellar disease. Thus in a general point of view, the cerebellum becomes a highly important, but *indirect* factor in normal motility.

Such is a brief, and perhaps imperfect outline of the plea offered by Courmont in behalf of his theory of cerebellar functions, intended to take the place of what is held to be fairly well established by experimental researches and clinical observation, viz., that this organ is not connected with the phenomena of sensibility or thought, but only with those of coördination of motion, its influence being exerted especially upon those muscular actions that maintain the equilibrium of the body. That his theory is simplicity itself, goes without saying, that it is not altogether new, is shown by the author's reference to Jessen,[3] but it seems very doubtful, whether it will succeed in gaining acceptance in the place of what certainly seem to be logical conclusions as to cerebellar function, derived from generally admitted physiological and pathological facts. The author's work, however is a highly instructive example of the manner in which an enthusiastic and ingenious mind, bent upon establishing an *a priori* hypothesis in physiology, may find an abundance of material in every direction, that readily lends itself to supply the arguments in its favor.

There are many other points of interest connected with nerve physiology, that might well claim attention, especially those bearing on the special senses, but your kindly patience has already been taxed too much, to permit of any further trespass upon your time.

Summing up the progress made, not only in the physiology of the nervous system, but in all other fields of our science, we see in every direction a steady advance, a gradual, but no less certain and solid gain in our knowledge of the functional activity of the organism. And it is particularly gratifying, in fact a matter of just pride, to be able to note that the original investigations of American physiologists have added no little to this increase, the fruits of their scientific labors being fully equal in value to those of their foreign colleagues.

In conclusion, may we not express the hope, that now, with this new, independent Section of Physiology at their service, they may in future select its meetings and proceedings as the channel, through which they can most appropriately communicate the results of their observations and research to the scientific world?

To Remove Nitrate of Silver Stains from the Fingers.—First paint the blackened parts with tincture of iodine; then, by applying ammonia, the iodine will be bleached, leaving white instead of black stains of nitrate of silver.

Canada has had a single examining board for more than twenty years. During this period it has licensed 1,300 regulars and 19 homœopaths.

PURULENT BRAIN DEPOSITS, AND PHLEBITIS AND THROMBOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

BY FRANK ALLPORT, M.D.,
OF MINNEAPOLIS, MINN.,
PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLOGY IN THE UNIVERSITY OF MINNESOTA, ETC.

(*Continued from page 604.*)

Case 135.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Male, age eight. Left ear. Chronic otorrhœa; vomiting; convulsions; paralysis of left upper eye-lid; limbs all weak; pain in left ear; dull; drowsy; semi-comatose; coma. Death.

Autopsy.—Abscess in left cerebral hemisphere.

Case 136.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Female, age twenty-six. Right ear. Purulent otorrhœa; delirium; episthotonos; coma. Death.

Autopsy.—Abscess in under surface of middle cerebral lobe.

Case 137.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Female, age fifty-one. Left ear. Purulent otorrhœa; cough; pain in limbs; pulse quick; convulsions; coma. Death.

Autopsy.—Abscess in left cerebral hemisphere.

Case 138.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Female, age twenty-three. Left ear. Epilepsy; convulsions; pain in head; fever; intense agony; convulsions. Death.

Autopsy.—Abscess. Coagulum of fibrin and blood in left lateral sinus.

Case 139.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Male, age fifty-four. Right ear. Epilepsy; pain in forehead; stupor; lost consciousness and sensibility; convulsions. Death.

Autopsy.—Abscess in middle lobe of right hemisphere.

Case 140.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Female, age seven. Left ear. Purulent otorrhœa; great debility; epilepsy after syringing; epilepsy continued. Death.

Autopsy.—Abscess in under part of left lobe of the cerebellum.

Case 141.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Male, age not given. Right ear. Purulent otorrhœa; cessation of discharge; chills and collapse; pain in right side; stupid; coma. Death.

Autopsy.—Abscess in right middle lobe.

Case 142.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Female, age twenty-six. Right ear. Chronic otorrhœa; pain in ear; headache; dizziness; coma. Death.

Autopsy.—Abscess in upper part of right cerebral hemisphere.

Case 143.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Female, age nine. Left ear. Purulent otorrhœa; fever; vomiting; pain in ear; paralysis of left side; coma. Death.

Autopsy.—Abscess in middle lobe of left side of cerebrum.

Case 144.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Male, age thirty-two. Chronic otorrhœa; chills; fever; abscess behind ear; stupor; convulsions. Death.

Autopsy.—Abscess in middle cerebral lobe. Pus between diseased mastoid and dura-mater.

Case 145.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Male, age thirty-five. Right ear. Chronic otorrhœa; caries of the mastoid; polypus in external meatus; pain in back of head, neck, and shoulders of the right side; stupor; coma. Death.

Autopsy.—Abscess in right lobe of cerebellum.

Case 146.—Extract from Treatise on the Ear, by Roosa. Reported by Gull and Sutton. Male, age thirteen. Right ear. Purulent otorrhœa; fever; headaches; thick speech; hemiplegia; vomiting; drowsiness; pain; stupor. Death.

Autopsy, Three abscesses in right lobe of the cerebellum.

Case 147.—Extract from Treatise on the Ear, by Roosa. Treated by J. Orne Greene. Male, age twenty-eight. Right ear. Chronic otorrhœa; paralysis of the muscles of face after walk in rain; pain on right side of head; vertigo; chills; nausea; vomiting; coma. Death.

Autopsy.—Abscess in right half of the cerebellum. Roof of tympanum bare, but not carious.

Case 148.—Extract from Treatise on the Ear, by Roosa. Treated by J. Orne Greene. Male, age twenty-two. Right ear. Acute purulent otorrhœa; pain in ear; headache; difficulty in swallowing; vertigo; paralysis of right hypoglossal nerve.

Autopsy.—Meningitis. Caries of inner table of skull. Cochlea, and semi-circular canals filled with solid red mass.

Case 149.—Extract from Treatise on the Ear, by Roosa. Treated by Farwick. Female, age thirty-six. Left ear. Chronic otorrhœa; pain in ear and left side of head; vertigo; delirium. Death.

Autopsy.—Abscess in left cerebral hemisphere. Caries of the roof of tympanum.

Case 150.—Extract from Treatise on the Ear, by Roosa. Treated by Schwartze. Female, age eighteen. Left ear. Chronic otorrhœa; pain in ear; chills; region of left jugular sensitive; pain in swallowing; nausea; uvula œdematous; vomiting; singultus; left side of neck œdematous and painful on pressure. Slight convulsive movements of the left arm. Death.

Autopsy.—Clots in superior longitudinal and superior petrosal sinuses. Old thrombus in left lateral sinus.

Case 151.—Extract from Treatise on the Ear, by Roosa. Treated by Schwartze. Male, age three. Left ear. Purulent otorrhœa; meningitis. Death.

Autopsy.—Œdema of pia-mater. Left lateral sinus contained a thrombus. Carious bone in left auditory canal.

Case 152.—Extract from Treatise on the Ear, by Roosa. Treated by Schwartze. Female, age fifty-four. Right ear. Chronic otorrhœa; pain in ear and head; vomiting; vertigo; coma; ptosis of right side. Death.

Autopsy.—Hyperæmia of membranes of brain. Oedema of pia-mater. Thrombus in right superior petrosal sinus.

Case 153.—Extract from Treatise on the Ear, by Roosa. Treated by von Tröltsch. Male, age fifty-three. Left ear. Chronic otorrhœa; polypus; pain in ear and head; coma. Death.

Autopsy.—Abscess in left middle cerebral lobe, connecting with petrous bone.

TABULAR REPORT OF PURULENT BRAIN DEPOSITS, AND PHLEBITIS AND THROM-

No.	Where Reported.	Surgeon's Name, etc.	Sex.	Age.	Ear.	Previous History.

BOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

Present History.	Result.	Autopsy.
Deafness; bony narrowing of meatus; pain in head; chills; temp. and pulse medium; slight delirium; mastoid opening; found pus	Death .	Necrosis found on outer surface of mastoid, squamous, frontal and sup. maxilla; on inner surface of squamous; on upper part of petrous; on petrous *over middle and internal ears; on inner plate of mastoid. Pus* found on outer surface of mastoid, squamous, frontal, and sup. maxilla. Pus generally distributed over left side of brain and first frontal fissure, first frontal convolution, fissure of Rolando, middle lobe on right side, both lateral ventricles, medulla and pons. Abscess on cerebellum. Ab*normal openings existed through inner mastoid plate*, through squamous, and between middle and internal ears and cranial cavity.
Pain in right side of head and ear; temp. and pulse medium; delirium; tender mastoid; mastoid opened; no pus found; squamous trephined; no pus found; skull trephined through mastoid and occipital bones; found pus	Death .	Abscess of cerebellum. Pus around medulla. Dura-mater inflamed and adherent. Pia-mater inflamed. Carious opening in *mastoid plate (inner)*. Carious opening between middle and internal ears and cranial cavity. Thrombi found in longitudinal sinus, Sylvian fissure, sup. petrosal sinus and right ventricle.
Pain in right side of head; temp. and pulse medium; delirium; mastoid swelled and inflamed; mastoid opened; found pus .	D'ath fr. ty'd fev.	Dura-mater congested and adherent. Pia-mater congested. Thrombi in longitudinal and lateral sinuses.
Pain in right side of head; temp. and pulse high; chills; delirium	Death .	Necrosis of tympanum and lateral sinus. Ossicles gone. Pus in sup. petrosal and lat. sinuses. Dura-mater and pia-mater inflamed. Thrombus in sup. petrosal sinus.
Temp. medium and sub-normal; pulse medium; pain in right ear, mastoid, and right side of head; mastoid swelled and tender; delirium; bowels loose; mastoid opened.	Death .	Diffuse subdural abscess. Most marked in anterior parietal region, anterior to fissure of Rolando. Collections *of pus on surface of* r. frontal convolution, and r. temporal convolution. Purulent thrombus in the sup. sinus and in sup. longitudinal sinus. Adhesions between arachnoid and pia-mater. Carious opening from mastoid cells into lateral sinus.
Diarrhœa; chills; delirious; aphasia; incoherence; swelling under mastoid in neck; temp. and pulse medium	Death .	Large vessels of dura and pia-mater filled with dark blood. Basilary artery and circle of Willis in same condition. Inferior surface of cerebellum purulent. Middle and internal ears purulent. Purulent thromus in l. petrosal sinus, both sup. and inf. Same condition in lateral sinus and internal jugular vein. Purulent phlebitis of external jugular vein. The vein from auditory canal in the same condition. Pus in semi-circular canals. Thrombus of basilar vein. Superficial posterior auricular glands much enlarged.
Temp. and pulse medium; temporal swelling *incised* and pus liberated; cheek *incised and* pus liberated; mastoid muscle *incised* and pus liberated; mastoid opened and pus liberated; delirium; right pupil contracted; stupor; unconsciousness; spasms of l. upper and lower extremities; l. facial paresis . .	Death .	Multiple pus sinuses in neck. Carious spots on outside of mastoid and occipital. Congestion of dura and pia-maters. R. sigmoid sinus, bulbous portion of jugular vein, and *mastoid* emissory vein, all obliterated. Tumor in *middle ear. Malleus and incus gone. Pus in* mastoid antrum. Carious canal leads from mastoid antrum into sigmoid fossa. Carious opening through incisura Santorini. Caries of pyramid. Caries of bony wall of transverse sinus.
Vertigo; *pain in head*; marked in occipital region; temp. and pulse sub-normal; polypus in r. ear; removed; l. ear; chronic otorrhœa; simple; coma	Death .	Hyperæmia of all meningeal veins. Carious opening in sup. petrosal *sinus over vestibule. Petrous* bone carious. Semi-circular canal, vestibule, and cochlea carious. Pus in middle cranial *fossa running into the* canal of the medulla. Abscess in left posterior cranial fossa. Cholesteatoma in l. mastoid antrum.
Chills; painful spot on top of head; meatus narrowed; headaches; temp. medium; mastoid opened; found pus; paresis of r. side of face; difficult speech; defective memory; aphasia; diagnosis; brain abscess; operation; fistula directly above meatus enlarged; pus found	Recov'y	
. . . .	Death .	Cerebral meningitis. Abscess of l. temporal lobe.
Earache; head painful; vomiting; paraplegic; *motor paralysis* of lower limbs; scalp and spine painful to touch	"	*Abscess beneath dura-mater* on anterior surface of petrous bone. Drum-head and ossicles gone. Pus in middle ear, mastoid *cells, and labyrinth. Pia*-mater congested. Vertebræ in portions of cervical and dorsal spine carious.
R. facial paralysis. *Painful mastoid*	"	Pus in middle ear and mastoid cells. Ossicles gone. Caries of tympanic walls. *Dura-mater* red, thickened and softened. Facial *nerve* and chorda tympani largely destroyed.
. . . .	"	Pus in middle ear, mastoid cells, vestibule and cochlea. Abscess in outer half of r. cerebral hemisphere.
Acute exacerbation; pain over *r. side of head*; meatus red; chills, fever, vomiting, headache; optic nerves congested; convulsions, unconsciousness, coma	"	Longitudinal sinus filled with blood. Abscess in temporal lobe. *Not encapsulated. Pus* in lateral sinus. Opening in anterior and outer wall of lateral sinus. Thrombus in *lateral sinus. Pus in tympanum* and mastoid cells. Malleus and incus carious.
Mastoiditis; convulsions	"	Abscess of cerebellum. Pus between dura-mater and tegmen-tympani.
Acute otitis	"	Pus over the region of the petrous bone, extending from the tympanic cavity through openings in tegmen-tympani.
Earache and headache; chills; temp. high; pain in temporal region and over r. eye	"	Abscess in anterior lobe of l. cerebellum. Caries of petrous bone. Clotted blood in lateral sinus. Carious opening in wall of lateral sinus, communicated with abscess.
. . . .	"	Congestion of dura-mater. Puro-lymph in pia-mater over l. sphenoidal lobe. *Abscess* in l. lobe of cerebellum. Temporal bone necrosed, especially in tympanum. Pus in middle ear. Drum-head gone.
Unconscious; maniacal; r. pupil contracted; mastoid swelled; Wilde's *incision*	"	Meningitis. *Abscess of l. lobe of* cerebellum. Almost entire destruction of anterior wall of ex. *meatus. Drum-head* gone. Caries of middle ear.
. . . .	"	Abscess communicating with middle ear in tempero-sphenoidal lobe.
Deafness; purulent discharge from ear; l. facial paralysis . . .	"	Caries in *tympanum. Abscess in* l. middle crus-cerebelli, extending partly into cerebellum and into pons, abutting on fourth ventricle and pressing on seventh nerve.
Acute exacerbation; mastoid abscess; opened; vomiting; semi-consciousness and facial paralysis; divergent strabismus; pupils contracted	"	Caries extending backward and upward from mastoid as far as parieto-occipital suture. Opening through parieto-occipital suture, leading into skull. *Lateral sinus empty and hard.* Meninges congested. Pus in posterior fossa between dura and skull. Caries at this point. Abscess of r. lobe of cerebellum.
Pain, especially in l. side of forehead; languid *and drowsy*; vomiting, aphasia, epilepsy	"	L. sphenoidal lobe adherent to bone. *Abscess in* l. sphenoidal lobe. Petrous carious in two places, one through roof of tympanum, the other in groove for lateral sinus. *The latter* communicated with mastoid cells.
. . . .	"	Abscess in r. lobe of cerebellum.
Pain and deafness; discharge; vomiting and dizziness; mastoid painful; fever.	"	*Pus at base of middle* lobe of cerebrum. Tympanum purulent, granular, and carious. Drum-head gone.
Headache, fainting, [illegible] ysis; paralysis of [illegible] meatus chiselled a[illegible] and fluctuating; pus between dura and pia	"	Purulent degeneration of dura, especially from longitudinal *sinus to base* of brain.
Headache, starting on l. side; feeling *of pressure*; *stupid*, aphasia; head drawn downward into neck; face red, pupils sluggish; constipation; *polypi in both* ears; removed; spasms; unconsciousness; flexion of all four extremities; *delirium*, stupor, *sensitive* skin, pain upon moving back	"	A yellowish projecting spot existed somewhat above surface of dura, over *the crista sup. of the petrous bone*, corresponding to site of injury. *Pia*, at convexity, covered with *pus*. Abscess in l. tempero-sphenoidal lobe. Pus in ventricle. An opening existed outward from the corpus *striatum* [illegible] scess. Purulent degeneration of temporal *lobe* and softened. Lateral ventricle as well as 3rd [illegible] Pia at base charged with pus, extending down into vertebral canal. Both mastoids filled with pus.
Pain; red mastoid; chills; unconsciousness; mastoid opened; pyæmia; herpes *on face*	Death .	Thrombi in l. lateral sinus and jugular vein.
Acute exacerbation, meningitis	"	Pus in tympanum. Opening through drum-head. Thrombo-phlebitis of transverse sinus. Abscess in subdural space and l. temporal lobe. Purulent lepto-meningitis of the base and convexity.

BOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

Present History.	Result.	Autopsy.
Appearance of cerebral symptoms after knock on head	Death .	Pus in tympanum. No perforation of drum-head. Incus gone. Caries of petrous bone through tegmen-tympani. Abscess in r. *temporal lobe.* Encapsulated. Thrombo-phlebitis of r. transverse sinus.
R. facial paralysis, vomiting, retained urine, dilated pupils, coma	“	Pus in tympanum. Perforation of drum-head. Caries of tegmen-tympani and ex. meatus. *Inspissated exudation compresses facial nerve* in Fallopian canal. Purulent basilar meningitis. Abscess in r. temporal lobe. Encapsulated. Mastoid sclerosed.
Polypus removed; headaches; mastoid opened; meningitis . .	“	*Epithelomia of l. middle ear, with destruction of most of temporal bone.* Purulent basilar meningitis.
Meningitis	“	Drum-head gone. Pebble in tympanum. Pus in tympanum. Purulent *meningitis of convexity.*
Vomiting, pain, convulsions	“	Caries of tegmen-tympani. Perforation of dura-mater near transverse sinus. Abscess of temporal lobe.
Headache, nausea, paresis of lower extremities	“	Abscess in r. lobe of cerebellum. Caries of petrous at internal aud. meatus. Pus in mastoid.
Pain in ear and head; deaf [illegible] ge; convulsions, delirium, coma [illegible] scle . . .	“	Necrosis in tympanum and ex. meatus. Dura near temporal bone injected, *thickened, and purulent.*
Pain in l. ear; cessation of [illegible] vertigo, high fever; thrombus felt in l. jugular; pain in neck; apathy; mastoid red and swelled; facial veins enlarged	“	Thrombi in transverse sinus and bulbous venæ jugularis. *Caries of jugular fossa.*
Granulations in tympanum; removed; later had pain in ear; cessation of discharge; return of bad symptoms; contraction of l. pupil; nystagmus of both eyes; somnolence; deafness; paresis of l. leg; paralysis of l. abducens; pain in all branches of trigeminus; vomiting	“	Pus around chiasm. Anterior extremity of l. lobe of *cerebellum is adherent* to posterior margin of temporal bone. Abscess in l. pons. At sup. border of temporal bone are three carious openings communicating with irregular cavity involving the entire posterior portion of temporal bone. This cavity is filled with a mass which infiltrates the posterior wall of temporal bone just above sigmoid sulcus, and is also connected with vestibule. Ossicles gone. *Int. ear destroyed by gelatinous mass.*
Pain in ear and side of head; acute catarrhal otitis; delirium; drum-head punctured; no pus	Death .	Congestion of dura at roof of tympanum. Sero-purulent exudation in sub-arachnoid space, extending from longitudinal fissure down side of brain. Pus in *upper surface of r.* lobe of cerebellum. Pseudo-membrane in tympanum.
Tinnitus aurium; pain, deafness, unconsciousness, convulsions	“	*Basilar meningitis.*
Pain; tinnitus aurium; found dead in bed.	“	Diffuse meningitis.
Traumatic inflammation of middle ear.	“	Basilar meningitis.
L. side of neck swelled; swelling *incised and pus evacuated;* pus comes from meatus on pressure of swelling; polypus in middle ear; middle ear connected by sinus with swelling; mastoid too sclerosed to open; chills	“	Coagulated blood in left sinuses. Localized meningitis. Clot in jugular *vein. Caries of atlas and 2d vertebra.* Pus in cavum tympanum. Occi*pital condyles carious.* Pus in mastoid cells. *Transverse sinus surrounded* by pus. Carious opening between mastoid antrum and sigmoid sinus.
Pain in ear and side of head; fever; deafness; tympanic granulations; removed; headache, exophthalmia, *ptosis; pain in* head; painful swelling over mastoid muscle; coma	“	Dura adheres to bone. Pus in subdural space. Pus *covers trigeminus* and acoustic nerves. Dura at base covered with pus. Pus in sup. petrosal sinus, *inferior cavernous sinus,* and transverse *sinus. Caries of* tegmen-tympani. Pus in tympanum. Thrombi in longitudinal sinus and communicating veins. Abscess in inferior posterior side of frontal lobe.
Caught cold; increased discharge and pain; attacks of unconsciousness, with loss of speech; convulsions; twitching of r. side of face; semi-conscious; fits, drowsy, *incoherent;* tenderness on pressure, most marked about two inches above meatus; slight facial paralysis; operation; skull trephined two inches above and one-half inch in front of meatus; trephined again one inch behind original opening; pus found *outside of dura;* trephined again over occipital parietal region. No pus; dura always left intact	Recov'y	
Pain in ear and side of head; chills, vomiting, *dizzy; aural* polypus; temperature medium; delirium; twitching of l. eyebrow and angle of mouth; retention *of urine;* semi-conscious; operation; trephined one and one-half inches behind meatus, and the *same* distance above the cerebral base line; pus evacuated; improvement; delirium, chills; *wound* re-explored; no pus; mastoid opened; no pus; paralysis of r. arm and leg; l. optic neuritis; track of original operation freely dilated: pus escaped	Recov'y	
Pain in ear, [illegible] -sided headache, [illegible] fused; delirium, unconsciousness, temp. and pulse high, coma, convergent strabismus l. eye, iris unresponsive	Death .	Polypus *of* ex. meatus. Semi-circular canals carious. Abscess of middle lobe of cerebrum, directly *above semi-circular canals.* Opening in meninges and brain tissue connecting the semi-circular canals and abscess.
Fever, apathetic, *half comatose,* paralysis and anæsthesia of l. leg, delirium; *mastoid opened;* no pus, *coma,* hemiplegia, hemi-anæsthesia	“	Carious opening through tegmen-tympani. Abscess between dura and petrous. R. cerebral hemisphere covered with pus. *Perforation of dura upon* posterior surface of petrous.
. . . .	“	Diffused abscess of r. lobe of cerebellum. Tympanum carious. Carious opening through tegmen-tympani.
Acute exacerbation, fever moderate, giddy, pain in jaw and behind ear, vomiting, *chills, pain in frontal* and occipital regions, pain in back, head retracted, r. facial paralysis, constipation, stupor, vomiting	“	Pia congested. Purulent exudation in frontal convolution of both sides. Pus at base in region of medulla. Brain adherent near r. internal auditory meatus. *Granulations in* tympanum and *mastoid* antrum. Malleus and incus gone. Facial nerve disorganized and denuded of its bony covering. Mastoid cells *obliterated and converted* into sclerosed mass. Pus in antrum. Caries of tympanum. Caries of cribriform lamina. *Carious* aperture on upper part of petrous communicates with cochlea. Bone over sup. semi-circular *canal is* carious.
Fever, bilateral optic neuritis, vomiting, unequal *pupils;* mas*toid* opened; improvement, but unequal pupils and optic neuritis persisted; stupor, insomnia, delirium, chills; operation; skull trephined 1¼ inches behind and 1¼ inches above center of meatus; aspiration needle [illegible] lobe inward, forward and downward	Recov'y	
Pain in ear and head, especially in [illegible] pain, *swelling* and fluctuation in l. o[illegible] at this point; pus liberated, bone de[illegible] improvement; later become worse; pus in occipital *region* came from interior of skull; frontal headaches, insomnia, nausea, pale, chills, fever, swelling *below original* opening incised; pus found [illegible] [illegible]itis both eyes; [illegible] original openin[illegible] [illegible]nial cavity; pa[illegible] [illegible]headache, nausea, vomiting, delirium, coma	*Death* .	The openings in the skull referred to in the history of the case were found. At outer *surface* of lateral sinus a *streak* of pus led along the transverse sulcus to large collection of pus at lowest part of sigmoid fossa. Pus in mastoid cells and tympanum. Abscess in middle and outer *part of little* brain. Not encapsulated.
Vertigo, pain in r. parietal region and ear, neuralgia in third *branch* of r. trigeminus [illegible] and middle ear, l. *arm* [illegible] vision, constipation, co[illegible]	Death .	Fluid blood in all sinuses. Pia *congested.* R. temp. lobe adherent to *petrous.* Abscess in r. temp. lobe. Encapsulated. Surrounding brain substance sclerosed. L. optic nerve atrophied. Perforation *through* anterior surface of r. petrous and dura. Carious opening in semi-circu*lar canals.* Drum-head and ossicles gone. Tympanum necrosed so that it and mastoid antrum are thrown into one cavity, all filled with *choles*teatoma.
Fever, loss of *appetite,* vomiting, paralysis of l. arm, epilepsy, chronic convulsions, r. pupil dilated	“	Abscess in r. first frontal convolution. Encapsulated. Roof of r. tympanum inflamed. Granulations in r. tympanum and mastoid cells. *Drum-*head destroyed. Ossicles *intact.*

BOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

Present History.	Result.	Autopsy.
	Death	Purulent thrombus in L. transverse sinus. Pus in jugular sinus, and defect in its anterior wall leads to necrosed petrous. Cholesteatoma in tympanum. Fibrous tissue about jugular vein infiltrated with serum and pus.
	"	Purulent infiltration of inner membranes of brain.
	"	Abscess in l. cerebellum.
Died of meningitic symptoms after illness of 16 days	"	L. trigeminus acousticous and facialis imbedded in pus. Purulent pia-mater. Thrombus in sup. sinus. Caries of petrosal sinus canal. Polypus in tympanum. Mastoid cells absent. Thrombas in lateral sinus.
Death from tubercular meningitis	"	Partial necrosis of l. wall of lateral sinus. Carious openings of bony walls of sulcus transversus.
	"	Ossicles gone. Caries of mastoid process. Caries of parietal bone.
	"	Multiple caries on skull. L. drum-head gone. Malleus and incus gone. Necrosis of mastoid process.
Painful mastoid, fever and chills, pain in l. temple, delirium	"	Anterior l. hemisphere covered with pus, extending to base of brain. Dura over l. tegmen-tympani discolored and pierced by openings, beneath which a cavity of pus was seen. Tegmen-tympani perforated by caries. Abscess in brain over tegmen-tympani, extending into lateral ventricle, which, with r. and middle ventricle, was filled with pus. Spinal cord bathed in pus. Polypus and necrosis in tympanum. Mastoid sclerosed.
Pain in entire head; polypus in l. tympanum	Death	Purulent meningitis at posterior cerebral fossa. Abscess in l. cerebellum. Caries of bony wall of facial canal. Caries of semi-circular canal. Mastoid sclerosed.
Meningitis; swollen mastoid; Wilde's incision; pus liberated; delirium, coma	"	Pus patches over brain surface. Pus at base of brain, especially at r. of cerebellum. Abscess in middle cranial fossa. Pus at sella turcica and and l. middle cranial fossa. Necrosis of tegmen-tympani. Tympanum carious. Mastoid sclerosed.
Pain in head	"	Suppurative meningitis over r. petrous bone. Inner mastoid at lateral sinus carious. Thrombus in lateral sinus. Abscess of r. tempero-sphenoidal lobe and occipital lobe. Abscess in r. cerebellum. Incus and stapes gone.
Painful ear; tinnitus aurium; drum-head perforated; mastoid swollen, red and painful; mastoid opened; pus found; not much fever	"	Abscess in l. middle lobe. L. sided pachymeningitis. Petrous carious, especially at outer half of middle surface. Pus in lateral ventricle of r. side of brain.
Mastoid symptoms; mastoid opened; pus found		Meningitis. Pus in neck between mastoid and styloid process. Caries in inner plate of mastoid at sulcus of lateral sinus. Caries of squamous. Lower surface of mastoid has 3 carious perforations in the groove next the tip of mastoid in the digastric fossa, all communicating with the carious mastoid cells. Mastoid antrum carious.
He discovered in the course of an operation for mastoid abscess, an abscess in the occipital lobe, which he opened	Recov'y	
Pyæmia, following a suppurating ear	Death	Thrombus in lateral sinus.
Meningitis	"	L. circumscribed basilar meningitis. Fistula between mastoid antrum and sup. petrosal sinus. Polypus in tympanum. No mastoid cells.
	"	Caries of tympanum, antrum, mastoid cells, and osseous walls of lateral sinus. Thrombosis of lateral sinus. Tubercular meningitis.
	"	Caries of tympanum and antrum. Carious opening through outer wall of mastoid. Caries of parietal bone. Meningitis.
	"	Necrosis of antrum and squamous. Meningitis
Chills, headache, thoracic pains, unsteady gait, constipation, night sweats, pupils dilated, delirium, coma, temp. and pulse not high	"	Double pleurisy. Pus in lungs, r. internal jugular vein, and tympanum. Abscess at apex of petrous bone. Necrosis of petrous near labyrinth. Blood coagulum in sigmoid sinus.
Headache, vertigo, vomiting, dilated pupils, temp. and pulse medium, chills, involuntary defecation, cough, thoracic pains, coma, convulsions	"	Congestion of pia-mater. R. cerebellum adherent to dura. Abscess in r. cerebellum. Tubercular deposits in brain. Thrombus in r. internal jugular vein, sub-clavian vein, vena-cava, and r. auricle. Pus in r. half of posterior occipital fossa, r. sigmoid sinus, tympanum, vestibule, and semi-circular canals. Lungs abscessed.
Mastoid abscess; opened mastoid; found pus; death from hematemesis	"	Pus and granulations in mastoid cells and tympanum. Meningitis.
Mastoid abscess	"	Abscess in temporo-sphenoidal lobe.
Mastoid abscess	"	Phlebitis of lateral sinus.
Headache, slow and intermittent pulse, normal or sub-normal temp., contraction of l. pupil, paresis of all ocular muscles except external rectus, partial r. facial paralysis, paresis of r. arm with wrist-drop; mastoid opened; no pus; skull trephined above ex. meatus; brain pierced with trocar; pus found	Recov'y	
Acute otitis; drum-head lanced; pain and tenderness at junction of temporal and occipital bones; temp. medium	Death	Caries of tympanum. Pus in middle ear. 7th nerve exposed and imbedded in pus. No mastoid disease. Meningitis.
Acute exacerbation, pain in r. half of head, vomiting, epilepsy, contraction of r. pupil; mastoid opened; no pus, emaciation, incontinence of urine, stupor, somnolence; operation; parietal bone trephined; dura incised; no pus; trephined again, 1½ inches above and 1¼ inches behind the ex. meatus; needle passed 1½ inches deep, forward and inward; pus found	Recov'y	
Acute otitis media; acute meningitis; choked disc on same side	Death	Purulent meningitis at base of cerebrum and lower surface of cerebellum. No evidence that pus had extended from ear. Internal auditory canal showed streaks of pus following the course of nerve.
Neuralgia of all three branches of r. trigeminous, followed by r. facial paralysis; r. choked disc; later, purulent otitis, pain, mastoid inflamed; mastoid opened; pus found; œdema of r. side of face; skull trephined at posterior cranial fossa; no pus; mastoid opening enlarged backward; improvement, nausea, fever, headache, vomiting, unconsciousness	"	Diffuse purulent lepto-meningitis. Abscess in temp. lobe.
Pain over mastoid; Wilde's incision; brain complications	"	Caries of tegmen-tympani. Abscess of brain over tympanum.
Spontaneous opening in ex. mastoid plate; facial paralysis; improvement; became worse; pain, vomiting, drowsiness, constipation, optic neuritis, convulsions	"	Dura-mater adherent to petrous. Pus in cerebellum.
Acute otitis media; drum-head not perforated	"	Caries of tegmen-tympani. Basilar meningitis.
Headache, vomiting, ptosis, optic neuritis, sub-normal temp., semi-comatose; operation; skull trephined; dura incised; pus found	Recov'y	
Acute purulent otorrhœa; mastoid pain, swelling and tenderness; pain in head; ptosis r. eye; divergent squint right eye; both pupils dilated; coma; mastoid opened; pus found; improvement; later became worse; vision poor; optic discs swollen; fever, delirium	Death	Dura adherent to skull. Pus on surface of both sup. lobes. Purulent thrombi in lateral sinus.
Acute otorrhœa; mastoid operation	"	Purulent meningitis. Inner plate of mastoid carious and perforated. Inner surface of petrous covered with granulations.
Pain, dizziness, aural polypi, left-sided deafness, chills, headache, temp. and pulse medium, tenderness behind ear; later, chills and high fever; operation after Von Bergmann, viz.: from a point 4 c.m. behind ex. meatus in a line made with the lower margin of the orbit, ascend perpendicularly for 5 c.m. to reach point for trephening; no pus; mastoid opened; pus and cholesteatoma found	"	Pus in pia, covering surface of l. frontal and parietal lobes. Perforation of inner mastoid plate. Purulent thrombus in lateral sinus.

BOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

Present History.	Result.	Autopsy.
Hard swelling in front of ear necrosis; pain in l. cheek sis; pain in vertex and occipital region; carious bone discharged from ear; meatus very carious; later, the entire area of disease had fallen in, comprising the ex. meatus up to the level of the drum-head, exposing the tempero-maxillary articulation; condyle of the ramus of the jaw now exposed. The area of disease was now almost large enough to admit the closed fist; hernia cerebri appeared; paralysis of r. side with aphasia; constipation	" .	Destruction of bony and other tissues terrific; even aqueductus fallopii, semi-circular canal and carotid canal were exposed. Hernia of tempero-sphenoidal lobe.
Purulent otorrhœa; caries of attic, antrum and tympanum; lymphadenoma; facial paralysis	Death .	Inner wall of attic gone. Semi-circular canals exposed. *Caries of antrum* and mastoid cells. Purulent meningitis.
Painful swelling over ear; abscess opened; no fistula	"	Abscess of tempero-sphenoidal lobe. Encapsulated. Drum-head perforated. Upper meatus necrotic. Necrosis at juncture of mastoid and squamous. Caseous pus in meatus and *mastoid cells*.
Abscess above ear; opened; convulsions, coma.	"	Necrosis of floor of middle temporal fossa, corresponding to position of middle ear. Adhesion between brain and dura. Perforation of dura. Abscess in temp. lobe. Mastoid cells filled with cheesy debris.
Acute exacerbation, pupils contracted, aphasia, 7th nerve on l. side paralyzed, choked discs both eyes, necrosis l. ex. meatus, paralysis r. arm and leg; opening made into cranial cavity by way of meatus and mastoid; no pus found	"	Abscess in anterior and *middle lobes of l. hemisphere. Encapsulated.* Necrosis of petrous.
Acute exacerbation, par. vision of both eyes, both discs obe can be passed into cranial no pus.	"	Thrombi in r. *lateral and sup. longitudinal* sinuses. Caries in sulcus for lateral sinus. *Necrosis of sup. wall of petrous. Caries of meatus, tympanum*, and walls of mastoid.
Vertigo, coma	"	Abscess in l. cerebellum. Encapsulated.
Acute purulent otorrhœa, fever, fluctuating swelling of l. parotid gland; opened; found pus; pus may be forced from swelling into ex. meatus; coma	"	Pus under dura and arachnoid, and in antrum and tympanum. Purulent thrombus in sup. petrosal sinus. Ulcer in this sinus communicating with pyramid. Carious opening connects cranial cavity and tympanum, and mastoid antrum. Ulcer in transverse sinus. Ex. meatus carious.
Acute purulent otorrhœa, fever, polypus; removed; granulations; swelling of glands below ear, and frequent attacks of pain in entire l. half of head; vertigo; death from tuberculosis	"	Ex. meatus carious. Between bulbous venæ jugularis and bony portions of Eustachian tube there were two fistulas leading into pyramid. Tympanum carious and purulent. Internal wall of carotid canal carious. Thrombus in carotid artery. Cheesy pus in mastoid antrum.
Pain in vertex, deaf, drum-head gone, polypus, partial paralysis of auditory nerve, temp. and pulse nearly normal, constipation, stupor, delirium, unconsciousness, divergent strabismus, herpes on r. cheek	"	Dura congested. Purulent lepto-meningitis, especially at base. Communicating abscess in r. cerebellum. Encapsulated. Drum-head gone. Pus and polypus in tympanum. Ossicles gone. Chorda-tympani destroyed. Pus in Fallopian canal. Facial nerve exposed in tympanum. Facial nerve looks normal in tympanum, but from gangliform swelling to internal auditory meatus it is inflamed. Acoustic nerve presents the same general appearances. Pus in vestibule and cochlea. Petrous bone saturated with pus.
Meatus swelled; granulations and necrosis in tympanum; abscess opened; communication with tympanum established; improvement; later became worse; a fistulous opening existed just below ex. meatus, through which pus escaped; carious bone in this fistula; water injected into meatus escaped into mouth and fistula; vomiting, headache, aural hæmorrhage, fever, pain, delirium	Death .	The bone in region of middle ear has been changed into one large carious cavity. Opening into internal carotid artery. Cerebellum abscess communicating with carious cavity.
Pain in r. ear and r. side of head; mastoid swollen and tender; deaf; Wilde's incision; carious bone found; trephining refused; chills, delirium; mastoid opened; pus found; coma	Death .	Meningitis at convexity and base. Red inflammatory softening at apex of temporal bone. Upper surface of cerebellum inflamed. Pus in pia-*mater, arachnoid, tympanum, mastoid antrum and cells*, vestibule, semi-circular canals, Eustachian tube, and canal for tensor-tympani. Necrosis in tympanum. Incus and stapes gone.
Acute exacerbation; mastoid abscess; opened; found pus; no *improvement; fever slight; ptosis of r. eye; paresis of l. internal* rectus and l. orbicularis; veins r. side of head congested; r. mastoid muscle rigid; pain on pressure of vein passing through posterior condyloid foramen; dense stupor; pulse slow and feeble; constipation; operation; skull trephined 1½ inches above and ½ inch behind the center of ex. meatus; dura opened; dura and pia congested; aspiration needle passed toward eminence of petrous bone; pus found ¾ inch deep; at same time skull again trephined just above osseous boundary of ex. meatus, involving squamo-petrosal suture; abscess reached	Recov'y	
Unconscious, weak and slow pulse, optic neuritis, nearly mori-	Recov'y	
Vomiting, pain in head, stupor, *tremors, convulsions*	Death .	*L. tempero-sphenoidal lobe adherent* to bone beneath. Abscess in tempero-sphenoidal lobe. Encapsulated. Two carious openings in temporal bone; one through tegmen-tympani, the other in groove for lateral sinus, communicating with mastoid cells.
Vomiting, pain, coma, spasmodic contraction of flexors of arms and legs	"	Abscess in temporal lobe. *Polypus in tympanum.* Drum-head and stapes gone.
Aphasia, constipation, unconsciousness, paresis of r. side, coma	"	Abscess in l. temporal lobe. Carious fistulæ in roof of antrum, sigmoid flexure, and posterior wall of exterior meatus. All fistulæ communicate with mastoid cells.
Pain in mastoid and occiput, chills, vomiting, constipation . .	"	Pus beneath dura on posterior surface of l. petrous bone. The walls of the l. lateral sinus were thickened and detached from the bone by underlying pus. Mastoid cells filled with cheesy pus.
Temp. and pulse medium, pain in head and neck, œdema and tenderness over *mastoid, r. facial paralysis*, œdema of r. upper eyelid, delirium, anæsthesia r. half of face, diarrhœa	"	Caries of tympanum. Phlebitis of jugular vein. Thrombus in r. lateral sinus, extending in through inferior petrosal sinus to r. cavernous sinus, thence through circular sinus to l. cavernous sinus, which was filled with disorganized clots and pus.
Delirium, strabismus, diplopia, sudden rise and fall of temp., retinal veins large and tortuous	"	Thrombosis of lateral sinus and jugular vein. Lung abscess.
Acute otitis, pain in r. forehead and temple, chills, constipation, somnolence, impaired vision, delirium, sudden rise and fall of temp	"	Thrombosis r. lateral sinus and internal jugular vein. Phlebitis of emissary mastoid vein.
Pain in r. side of head	"	Thrombosis of *sigmoid flexure* and r. lateral sinus. Lepto-meningitis.
Chills, pain in occipit, vomiting	"	Phlebitis and thrombosis of lateral sinus. Meningitis. Cholesteatoma in mastoid cells.
Pain in ear, forehead and occiput, fever, œdema of temple, headache, stupor, spasms of upper extremities	"	Phlebitis and thrombosis of lateral and sup. petrosal sinuses. Circumscribed basilar meningitis.
External opening made over mastoid, vomiting, delirium, nose-bleed	"	Tubercular meningitis. *Thrombosis of l. lateral* ainus.
Furuncle l. meatus, pain in head	"	Inflammation of arachnoid and pia-mater. Abscess anterior portion of cerebellum. L. auditory and facial nerves *imbedded* in pus. Pus in mastoid cells. Slight tympanic inflammation.
Pain, facial paralysis; mastoid opened; caries of cells, antrum and tympanum; pyæmia	"	Carious openings into middle cerebral fossa and into transverse sinus. Phlebitis and thrombus of transverse sinus.

BOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

Present History.	Result.	Autopsy.
Acute purulent otorrhœa; meningitic symptoms, chills, temp medium, pulse low; Wilde's incision; delirium, pyæmia	Death	Fibrino-purulent exudation in pia. Congula in sinuses. Lateral ventricle dilated and filled with blood-stained serum. Tegmen-tympani carious. Lateral sinus carious.
Deaf, dizziness, headache, diplopia, partial paralysis, coma	“	Abscess in tempero-sphenoidal lobe. Necrosis tegmen-tympani. Sinus connecting auditory canal and cerebral cavity.
Pain, high fever	“	Pus under dura and in mastoid cells. Temporal bone infiltrated with pus. Drum-head, malleus, incus, and part of stapes gone.
Acute purulent otorrhœa, pain in r. side of head, delirium, retention of urine, temp. and pulse medium	“	R. optic nerve atrophied. Meninges at base of cerebellum and upper part of spinal cord, covered with lymph and sero-pus. Malleus and incus gone.
Acute purulent otorrhœa, pain behind ear and in head, stupor.	“	Dura congested. Lymph at base. Pus at base, extending to medulla.
Pain in head and ear, temp. and pulse medium, chills, pleurisy, pneumonia, pain over lateral sinus, exophthalmus	“	Thrombus of r. internal jugular. Pus in r. lateral sinus. Drum-head and ossicles gone. R. lateral sinus carious.
Paralysis of one side, ptosis, giddy, chills, drowsy, delirium, face flushed, head hot, convulsions	“	Abscess in center of r. cerebral hemisphere.
Head and neck rigidly curved forward, and spine curved; rotary movements of head; unable to swallow	“	Abscess in pons varolii.
Sore throat for one week, and became generally ill; chills, semi-coma	“	Abscess in middle lobe.
Paralysis of r. half of face; pain in r. side of head, drowsy, semi-coma	“	Abscess in middle half of r. lobe of cerebellum, communicating directly with diseased temporal bone.
Caries of temporal bone, chills, pain in head, vomiting	“	Abscess in r. lobe of cerebellum.
Frontal headache, vertigo, delirium, paresis of l. side, coma	“	Abscess in r. middle lobe of cerebrum.
Pain in r. side of head and r. ear, vomiting	“	Suppuration and sloughing of r. middle lobe of hemisphere.
Paralysis of r. 7th nerve, pain in head, pain on moving neck, chills, nausea, vomiting, sweating	“	Abscess in cerebellum.
Syncope, convulsions with insensibility, pain in head, nausea, delirium, convulsions, pain and cramp in l. leg, coma	“	Abscess of the posterior lobe of r. hemisphere.
Delirium, coma	“	Abscess in anterior and middle lobe of l. hemisphere, communicating with carious petrous.
Pain in head, paralysis of r. side of face; death from hæmorrhage from lateral sinus	“	Dura inflamed, Sloughing of brain tissues. Lateral sinus inflamed and sloughy.
s of l. upper eyelid, limbs weak, -coma, convulsions	“	Abscess in l. cerebral hemisphere.
	“	Abscess in under surface of middle cerebral lobe.
Cough, pain in limbs, pulse quick, convulsions, coma	“	Abscess in l. cerebral hemisphere.
Convulsions, pain in head, fever, agony, convulsions	“	Abscess. Congulum of fibrin and blood in l. lateral sinus.
Pain in forehead, stupor, lost consciousness and sensibility, convulsions	“	Abscess in middle lobe of r. hemisphere.
Debility, epilepsy	“	Abscess in under part of l. lobe of cerebellum.
Cessation of discharge, chills and collapse, pain in r. side, stupid, coma	“	Abscess in r. middle lobe.
Pain in ear, headache, dizzy, coma.	“	Abscess in upper part of r. cerebral hemisphere.
Fever, vomiting, pain in ear, l. sided paralysis, coma	“	Abscess in middle lobe of l. side of cerebrum.
Chills, fever, abscess behind ear, stupor, convulsions	“	Abscess in middle cerebral lobe. Pus between diseased mastoid and dura-mater.
Pain in back of head, neck and shoulders of r. side, stupor, coma	“	Abscess in r. lobe of cerebellum.
Fever, headache, thick speech, hemiplegia, vomiting, drowsy, pain, stupor	“	Three abscesses in r. lobe of cerebellum.
Pain in r. side of head, vertigo, chills, nausea, vomiting, coma.	“	Abscess in r. half of cerebellum. Roof of tympanum bare, but not carious.
Pain in ear, headache, difficulty in swallowing, vertigo, paralysis of r. hypoglossal nerve	“	Meningitis. Caries of inner table of skull. Cochlea and semi-circular canals filled with solid red mass.
Pain in ear and l side of head, vertigo, delirium	“	Abscess in l. cerebral hemisphere. Caries of roof of tympanum.
Chills, left side of neck œdematous and painful on pressure, especially over jugular; painful swallowing, nausea, uvula œdematous, vomiting, singultus, convulsion of l. arm	“	Clots in sup. longitudinal and sup. petrosal sinus. Old thrombus in l. lateral sinus.
Meningitis	“	Œdema of pia-mater. L. lateral sinus contained a thrombus. Carious bone in l. auditory canal.
Pain in ear and head, vomiting, vertigo, coma, ptosis of r. eye	“	Hyperæmia of membranes of brain. Œdema of pia-mater. Thrombus in r. sup. petrosal sinus.
Pain in ear and head, coma	“	Abscess in l. middle cerebral lobe, connecting with petrous bone.
Brain symptoms	“	Carious perforation of roof of tympanum. Abscess of l. inferior cerebral lobe.
Chills, œdema near ear, swelling of sub-maxillary glands, delirium, r. pupil dilated, coma	“	Thrombus in r. lateral sinus. Caries of roof of tympanum.
Headache, vomiting, pain in ear and occipit, coma, delirium	“	Abscess in l. cerebellum and in l. inferior cerebral lobe.
Pain in ear	“	Sinuses congested. R. lateral sinus filled with a clot.
	“	Caries Lateral sinus filled with pus. Gangrene of brain.
Mastoid fistula, paralysis of facial nerve, brain symptoms	“	Abscess in r. middle lobe of cerebrum. Caries.
Chills, vomiting, pain in r. side of head, facial and pharyngeal paralysis	“	Abscess in r. middle lobe of cerebrum. Tegmen-tym- d soft. Caries of mastoid cells.
Mastoid fistula, vomiting, inanition, pneumonia, convulsions	“	Exostosis of petrous bone. Caries of tympanum and mastoid. Connective tissue growths in vestibule.
Temp. and pulse medium, pain in r. side of head, delirium, divergent squint, dilated pupils, coma	“	Purulent meningitis of frontal lobes. Pia opaque. Sulci filled with pus. Pus in tympanum.
Pain in mastoid and occipit, vertigo, high fever, later tumor formed over mastoid, extending to center of parietal and occipital bones; incision; pus foun ened; later, boring pains and h ough- r. exophthalmus; later, pneumo ision- deli, rium, unconsciousness, collapse	“	Caries of r. petrous. Rupture of sigmoid sinus. Thrombus of r. transverse sinus, both carotid sinuses, circular sinus of Ridley, l. cavernous sinus, sup. petrosal sinus, and r. ophthalmic vein. Purulent degeneration of thrombi, and inflammation of walls of above named sinuses. Purulent infiltration of connective tissue of r. orbit. Chronic œdema of pia-mater and arachnoid. Numerous pneumonic and gangrenous centres in both lungs.
Pain in l. side head and mastoid, Wilde's incision, no pus; later, coll ye-lid, exophthalmus, pupil sluggish; pus; later, swelling of r. eye-lid and r. eye-lid incised, found pus	“	Cholesteatoma of tympanum, mastoid cells, transverse sinus, and incisura mastoid of l. transverse sinus and jugular veins. Basilar coagulum in inferior petrosal sinus and caverno ophthalmic veins on both sides.
Pain in ear, vomiting, dizziness, chills, meatus swollen, pain and œdema over mastoid, and especially over mastoid foramen and adjacent occipital bone, temp. and pulse elevated; operation; mastoid opened, no pus, improved; later, pain and swelling over mastoid muscle	“	Purulent swelling over clavicle. Purulent mastoid periostitis. Sulcus of lateral sinus carious. Carious opening in tegmen-tympani. Thrombus in lateral sinus. Pus under dura-mater at sinus.
Swelling and redness over mastoid; pus came from an opening one-quarter of an inch in front of the membrana tympanum; pressure over mastoid caused the *pus to flow* more freely; operation refused	“	Pus in arachnoid space all over brain. Dura healthy. Upper anterior surface of *petrous carious*.
Diagnosis: Exudation in tympanum; made a paracentesis; removed serum later; a furuncle developed in the meatus; tympanic discharge became purulent; later, caught cold; pain in ear and head; temp. 104°; enlarged opening in drum-head; later, opening again enlarged; continued pain in head; vertigo, paresis of r. facial; aphasia; temp. medium; paresis of r. arm; operation; mastoid opened; no pus, no necrosis; roof of mastoid cavity opened, dura exposed; no pus; dura opened and brain exposed; no pus; exploratory puncture made, forward and upward, and pus evacuated; orifice enlarged by knife, and drainage tube inserted; cavity antiseptically irrigated; iodoform gauze used	Recov'y	

TABULAR REPORT OF PURULENT BRAIN DEPOSITS, AND PHLEBITIS AND THROM-

No.	Where Reported.	Surgeon's Name, etc.	Sex.	Age.	Ear.	Previous History.
168	*Arch. Otol., April, 1892*	*C. Truckenbrod, Hamburg* .	M	29	L	. . . .
169	*Arch. Otol., April, 1892*	*C. Truckenbrod, Hamburg* .	M	25	L	. . . .

Case 154.—Extract from Treatise on the Ear, by Roosa. Treated by Von Tröltsch. Male, age twenty-four. Left ear. Chronic otorrhœa; brain symptoms. Death.

Autopsy.—Carious perforation of roof of the tympanum. Abscess of the left inferior cerebral lobe.

Case 155.—Extract from Treatise on the Ear, by Roosa. Treated by Von Troltsch. Female, age twenty-one. Right ear. Chronic otorrhœa; chills; œdema in the vicinity of the ear; swelling of submaxillary glands; delirium; dilatation of right pupil; coma. Death.

Autopsy.—Thrombus in right lateral sinus. Caries of roof of tympanum.

Case 156.—Extract from Treatise on the Ear, by Roosa. Surgeon's name omitted. Female, age twenty. Left ear. Chronic otorrhœa; headaches; vomiting; pain in ear and occiput; coma; delirium. Death.

Autopsy.—Abscess in left cerebellum and in left inferior cerebral lobe.

Case 157.—Extract from Treatise on the Ear, by Roosa. Treated by Cock. Male, age thirty-five. Chronic otorrhœa; pain in ear. Death.

Autopsy.—Sinuses congested. Right lateral sinus filled with a clot.

Case 158.—Extract from Treatise on the Ear, by Roosa. Treated by Cock. Sex not given. Age twenty. Chronic otorrhœa; symptoms not given.

Autopsy.—Caries. Phlebitis. Lateral sinus filled with pus. Gangrene of the brain.

Case 159.—Extract from Treatise on the Ear, by Roosa. Treated by Schwartze. Female, age four. Right ear. Chronic otorrhœa; fistula of mastoid; paralysis of facial nerve; brain symptoms. Death.

Autopsy.—Meningitis basilaris. Abscess in right middle lobe of cerebrum. Caries.

Case 160.—Extract from Treatise on the Ear, by Roosa. Treated by Schwartze. Female, age thirty-four. Right ear. Purulent otorrhœa; chills; vomiting; pain in right side of head; facial and pharyngeal paralysis. Death.

Autopsy.—Fistula of mastoid. Abscess in right middle lobe of cerebrum. Tegmen-tympani discolored and soft. Caries of mastoid cells.

Case 161.—Extract from Treatise on the Ear, by Roosa. Treated by Schwartze. Sex not given, age eight months. Left ear. Purulent otorrhœa; fistula of mastoid; vomiting; inanition; pneumonia; convulsions. Death.

Autopsy.—Exostosis of petrous bone. Caries of tympanum and mastoid. Connective tissue growths in vestibule.

Case 162.—*Ophthalmic Record*, March, 1892. Treated by J. Morrison Ray, of Louisville, Ky. Female, age 47. Right ear. Acute purulent otorrhœa; temperature and pulse medium; pain in right side of head; delirium; ptosis; divergent squint; dilated pupils; coma. Death.

Autopsy.—Purulent meningitis of frontal lobe. Pia opaque. Sulci filled with pus. Pus in tympanum.

Case 163.—Politzer on the Ear, page 538. Treated by R. Chimani. Male, age 30. Right ear. Chronic otorrhœa; pain in mastoid and occiput; vertigo; high fever. Later, tumor formed over mastoid, extending to center of parietal and occipital bones; incision; pus found; underlying bones roughened. Later, boring pains and heat flashes; disturbed vision; right exophthalmus. Later, pneumonia; jaundice; vomiting; delirium; unconsciousness; collapse. Death.

Autopsy.—Caries of right petrous. Rupture of sigmoid sinus. Thrombus of right transverse sinus, both carotid sinuses, circular sinus of Ridley, left cavernous sinus, superior petrosal sinus, and right ophthalmic vein. Purulent degeneration of the thrombi, and inflammation of the walls of the above named sinuses. Purulent infiltration of the connective tissue of the right orbit. Chronic œdema of pia-mater and arachnoid. Numerous pneumonic and gangrenous centers in both lungs.

Case 164.—Politzer on the Ear, page 539. Treated by Burkhardt-Merian, of Basle. Female, age twenty-five. Left ear. Chronic otorrhœa; pain in left side of head, and mastoid; Wilde's incision; no pus. Later, collapse; swelling of left eye-lid; exophthalmus; pupil sluggish; mastoid opened; pus found. Later, swelling of right eye-lid, and right exophthalmus; upper eye-lid incised; found pus. Death.

Autopsy.—Cholesteatoma of tympanum, mastoid cells, transverse sinus, and incisura mastoidea. Thrombo-phlebitis of left transverse sinus and jugular veins. Basilar meningitis. Ichorous coagulum in inferior petrosal sinus and cavernous sinus. Phlebitis of ophthalmic veins on both sides.

Case 165.—Treated by J. Orne Greene. Female. Right ear. Chronic otorrhœa; pain in ear; vomiting; dizziness; chills; meatus swollen; pain and œdema over mastoid, and especially over mastoid foramen and adjacent occipital bone. Temperature and pulse elevated.

Operation.—Mastoid opened; no pus; improved. Later, pain and swelling over mastoid muscle. Death.

Autopsy.—Purulent swelling over clavicle. Purulent mastoid periostitis. Sulcus of lateral sinus carious. Carious opening in tegmen-tympani. Thrombus in lateral sinus. Pus under dura-mater at sinus.

Case 166.—*Edinburgh Medical Journal*, November, 1879. Treated by Kirk Duncanson. Male, age thirty-seven. Left ear. Acute otorrhœa; swelling

BOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

Present History.	Result.	Autopsy.
Pain over mastoid; temp. 103°; pulse 92°; drum-head injected; perforation of drum-head; violent pain in ear and head; painful mastoid; mastoid opened, pus liberated; transverse sinus seen at bottom of incision; later, violent pain in temporal region; divergent strabismus of l. eye; later, temp. 99°; pulse 55°; ptosis of l. upper lid; loss of sensibility over lower extremities; skull trephined at tempero-parietal region; dura tense; dura incised; puncture of temporal lobe; pus evacu- [illegible] ment; later became worse, coma, death	Death .	Pus at chiasm. Pus in lateral ventricles. Abscess in temporal lobe.
P [illegible] ing; mastoid tender; temp. 101°; mastoid opened, pus evacuated; improvement; suspended breathing; artificial respiration; successful; mastoid opening enlarged; dura exposed; exploratory needle introduced, upward and backward; pus evacuated	Death	Abscess of cerebellum. Pus in sulcus for transverse sinus. Thrombus in transverse sinus. Necrotic opening through tegmen-tympani.

and redness over mastoid; pus came from an opening one-quarter of an inch in front of the membrana tympanum; pressure over mastoid caused the pus to flow more freely. Operation refused. Death.

Autopsy.—Pus in arachnoid space all over the brain. Dura healthy. Upper anterior surface of petrous was carious.'

Case 167.—Archives of Otology, April, 1892. Treated by C. Truckenbrod, of Hamburg. Male, age fifty-four. Left ear. Previous history, deafness and tinnitus for ten days.

Diagnosis.—Exudation in tympanum; made a paracentesis; removed serum. Later, a furuncle developed in the meatus; tympanic discharge became purulent. Later, caught cold; pain in ear and head; temp. 104°; enlarged opening in drum-head. Later, opening again enlarged; continued pain in head; vertigo; paresis of right facial; aphasia; temp. medium; paresis of right arm.

Operation.—Mastoid opened; no pus; no necrosis; roof of mastoid cavity opened; dura exposed; no pus; dura opened, and brain exposed; no pus; exploratory puncture made, forward and upward, and pus evacuated; orifice enlarged by knife, and drainage tube inserted; cavity antiseptically irrigated; iodoform gauze used. Recovery.

Case 168.—Archives of Otology, April, 1892. Treated by C. Truckenbrod, of Hamburg. Male, age twenty-nine. Left ear. Previous history not given. Pain over mastoid; temp. 103°; pulse 92°; drum-head injected; perforation of drum-head; violent pain in ear and head; painful mastoid; mastoid opened; pus liberated; transverse sinus seen at bottom of incision. Later, violent pain in temporal region; divergent strabismus of left eye. Later, temp. 99°; pulse 55°; ptosis of left upper lid; loss of sensibility over lower extremities. Skull trephined at temporo-parietal region; dura tense; dura incised; puncture of temporal lobe; pus evacuated. Improvement. Later, became worse; coma. Death.

Autopsy.—Pus at chiasm. Pus in lateral ventricles. Abscess in temporal lobe.

Case 169.—Archives of Otology, April, 1892. Treated by C. Truckenbrod, of Hamburg. Male, age twenty-five. Left ear. Previous history not given. Pain; aural suppuration; vomiting; mastoid tender; temp. 101°; occasional unconsciousness; mastoid opened; pus evacuated. Improvement. Suspended breathing; artificial respiration; successful. Mastoid opening enlarged; dura exposed; exploratory needle introduced, upward and backward; pus evacuated. Death.

Autopsy.—Abscess in cerebellum. Pus in sulcus for transverse sinus. Thrombus in transverse sinus. Necrotic opening through tegmen-tympani.

(*To be continued.*)

BOOK REVIEWS.

TRANSACTIONS OF THE AMERICAN SURGICAL ASSOCIATION, *Volume Tenth. Edited by* J. EWING MEARS, M.D., Recorder of the Association. Philadelphia: 1892.

This volume of most excellent reports of papers read at the meeting of the Association, May 31, June 1, and 2, 1892, is singularly defective in making no mention so far as we can discover of the place where the meeting was held.

This volume is particularly valuable in that it contains a complete index of the papers read before the Association from its first organization to the last meeting.

Dr. P. S. Conner of Cincinnati, was the presiding officer at the late meeting.

Dr. Nicholas Senn, was elected President for the ensuing year, and Dr. J. R. Weist Secretary, but where and at what date the book before us does not tell.

A MANUAL OF MEDICAL JURISPRUDENCE. By ALFRED SWAIN TAYLOR, M.D., F. R.S., revised and edited by THOMAS STEVENSON, M.D., London. Eleventh American edition with *citations and additions* from the twelfth English edition, by CLARK BELL, Esq., President of the American International Medico-Legal Congress of 1893. 787 pages, 56 illustrations. Price, cloth, $4.50; sheep, $5.50. Lea Brothers & Co., Phila., 1892.

We have examined the above entitled work with more than usual interest, not only on account of the fact that it has gone through numerous editions and is well-known to the profession; but because in the preface of the learned American editor it is stated that much new matter has been added and a large number of authorities cited to aid council in preparing briefs, etc, A careful examination of the work shows that its value has indeed been enhanced, but we confess to a feeling of disappointment that the work has not been more thoroughly and exhaustively done. The author and English editor have cited very few American authors and those not always correctly. While perhaps this was to be expected of English authors, still the profession have a right to expect that an American who holds himself out as a member of so many learned societies as does Mr. Bell on the title-page, should remedy this defect and relieve the book of its insular character. The legal side of the editorial work has been more thoroughly done than the medical side, which is what one would naturally expect considering the fact that the editor is not a medical man. We are constrained to state, however, that much matter is included in the legal notes which, while valuable and interesting has no earthly bearing upon the subject of medical jurisprudence. This is notably the case with the note on expert evidence beginning on page 52, in which we learn among many other interesting but irrelevant things, that "masters of vessels or experienced seamen may give their opinions on questions pertaining to nautical science or affairs," to sustain which proposition, which no rational man would ever think of disputing at the present day, no less than twenty-two cases are cited.

On the other hand matters which, by reason of their importance merit an exhaustive treatment are merely touched upon or not even mentioned. The subject of malpractice for example, receives at the hands of the American editor only one and one-half pages, and even these show traces of hasty preparation.

References to American medical literature which abound in valuable and instructive cases (not in courts of law) are very few, so few as to lead one to believe that the field of periodical literature has not been explored by the editor.

For example, the subject of hypnotism is not mentioned in the index, and we have not found it treated in the text. Instances like the above might be multiplid.

Nothwithstanding all these indications of hasty or inadequate preparation of this edition, the work is still valuable but by no means so valuable as the profession have a right to expect.

A Manual of Organic Materia Medica, being a guide to materia medica of the vegetable and animal kingdoms, by John M. Maisch, Ph. M., Phar., D., fifth edition with two hundred and seventy illustrations. Philadelphia; Lea Brothers & Co. 1892.

The fact that a fifth edition of this excellent manual has been called for within two years of the publication of the fourth, is sufficient to confirm the value value of the work. Indeed, it has been so frequently reviewed and has become such a standard text-book, that any extended comment at this time is needless.

The present edition differs mainly from the former in the incorporation of the added knowledge upon this subject in the last two years, and the use of accent marks upon the systematic names of plants and animals. Several illustrations have been added, partly replacing others, further eludicating structural peculiarities.

We cannot let the occasion pass without commending the superior quality of press work shown in this volume. The wood-cuts show with surprising clearness.

Materia Medica and Therapeutics. By L. F. Warner, M.D. Philadelphia. Lea Brothers & Company.

This little work of 223 pages forms part of "The Students' Quiz Series," now being issued by Lea's. While we have heretofore expressed doubts of the value of works of this character they have undoubtedly come to stay. The work before us is admirably arranged in the form of questions and answers especially adapting it for the use of students classes in which one of their own number act as leader. It also facilitates brevity and conciseness of expression, a *sine qua non* in a work of this sort.

The author says that he has aimed at "a convenient and concise statement of the most important facts of materia-medica and therapeutics." A careful reading of his pages shows that he has achieved success upon these lines, and within the limitations imposed by the size of the work. There are important omissions, and perhaps we would differ from him in some of his conclusions but to state them would we think, be hypercritical in the light of our conflicting authorities.

Wisconsin State Medical Society. 1892.

The Annual Volume of Transactions of this organization indicates an excellent working Society. The papers show a spirit of research on the part of many of the members that is exceedingly commendable.

The President of the meeting was Dr. G. F. Witter, of Grand Rapids, and Dr. C. S. Sheldon, of Madison, the Secretary. For the ensuing year Dr. B. T. Phillips, of Menominee, Mich., was elected President, and Dr. C. S. Sheldon, of Madison, re-elected Secretary. Number of active members 332.

A Plea for Public Health in Villages.—When a fire breaks out in a village, every person considers it a duty to give a general alarm, and, especially, prompt notice of it to the fire departments, and all citizens coöperate for the speedy extinction of the fire. If this were not done, the property in the village would be quite generally endangered by the possible spread of the fire. Why is it that when a dangerous communicable disease breaks out—one which may spread and endanger quite generally the *lives* of persons in the village—there is, so frequently, no such general alarm and prompt notice to a well-organized department of the village government, and no general coöperation for the extinction of the disease? Is not a person's life of more consequence than his property? Is not the saving of the *lives* of their children of as much consequence to the inhabitants of the village, as the saving of their *property?* If each person were forced to answer this question, relative to his own children, I believe that he would feel like a degraded, miserly wretch if he did not promptly sacrifice his property in defense of the life of his child. Yet, collectively, the citizens generally do *not* do for the protection of *life*, what they do for the protection of *property*—they do not maintain a well-organized health department so generally as they do a well-organized fire department. I believe it is because they do not so generally know that lives may be saved by well-organized health departments, or because they do not know the value of human life to the community. —H. B. Baker, M.D., in *Annals of Hygiene.*

The Pan-American Medical Congress.—The appearance of the preliminary announcement of the first Pan-American Medical Congress, to be held in Washington next September, is at once a promise, a guarantee, and a call to action. Few have an adequate conception of the magnitude of this undertaking, and of its significance to American medicine. It is very evident that it has now entirely passed the stage of doubt or indecision. The first thought that strikes one in glancing through the pamphlet of the preliminary announcement is as to the tremendous business and executive demands made upon the officers, and that so far have been splendidly met by the energetic Secretary-General, the President, and others. The officering of the long lists of the Sections has been a work of the greatest difficulty and finest judgment, and one can only marvel at the excellence of the results.

But it is now time for all American physicians to respond to the invitation and the opportunity in a spirit of patriotism to our country and loyalty to our profession. It is not now a question of the success of the Congress, but as to whether we shall or shall not give that early and effective sympathy that constitutes each of us a helper and a part of the success. The heavy expenses of organization, amounting to something like $5,000, must be paid by the advance registration-fees. The Secretary-General is Dr. Charles A. L. Reed, Cincinnati, Ohio, who, upon request, will forward copies of the preliminary announcement. The Treasurer is Dr. A. M. Owen. Evansville, Ind., to whom should be remitted the registration-fee.—*Medical News.*

Ipecac in Uterine Inertia.—Drapes (*Der Frauenarzt*, March, 1892) says this remedy, in simple atony of the uterus, is a powerful agent in producing uterine contraction during the first and second stages of labor.

In general, two or three doses of from 10 to 15 drops of the wine of ipecac, given at intervals of ten minutes, produce, in a short time, marked activity of uterine action and a rapid birth. It is much better than ergot, as it does not produce tetanic contraction, but only induces normal and regular expulsive efforts.—*The Therapeutic Gazette*, July 15, 1892, p. 481.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES. . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1271, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1271, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, NOVEMBER 26, 1892.

THE ANTITOXIC PROPERTIES OF THE BLOOD OF CHOLERA CONVALESCENTS.

The researches of KLEMPERER (THE JOURNAL Oct. 29,) have shown, that while the blood serum of normal men possesses either no influence or but a very feeble one upon the toxicity of cultures of cholera bacilli a decided antitoxic effect is exerted by the blood of people who have been inoculated with cholera bacilli subcutaneously. The antitoxic effect of the blood serum of patients recovered from genuine cholera has now been tested by LAZARUS of Berlin, *Berliner klin. Wochenschrift*, Nos. 43 and 44, with remarkable results.

Our conception of the term immunity has gained in precision very much since clinical observations have been supplemented by laboratory work. From the earlier researches of PASTEUR on anthrax and chicken cholera it became evident that there may be different degrees of immunity. After BEHRING had discovered that an important—if not the most important factor in acquired immunity is the acquired antitoxic property of the blood, EHRLICH taught us how to measure this property and thus express the degree of immunity in terms of mathematical accuracy.

KLEMPERER found it possible to influence the economy by his inoculation with cholera bacilli under the skin to such an extent, that one-half to one cc. of the person's serum injected into a guinea pig protected the latter against a fatal dose of a cholera culture. In the natural immunity following convalescence from an attack of cholera LAZARUS found the antitoxic effect of the serum 5 to 10,000 times as great as in the blood of the vaccinated person. One-tenth of a milligram of the serum was sufficient to protect a guinea-pig against death while ½ m. gr. prevented even any transient effect of an otherwise fatal dose of virulent cholera-culture.

This marvellous antidotal influence occurs only if the protective injection is made before the poisonous cholera-toxines are injected into the peritoneum. After the introduction of the cholera poison protection can be had only from enormous doses of serum up to 1 cc. and from these only if they are given during the incubation period of the first few hours. After the effects of the cholera poison had become manifest by the lowering of the animal's temperature, no curative results could be obtained from serum in any quantity.

The author suggests that a trial might be made in man to utilize the antitoxic properties of the blood of convalescents during the premonitory diarrhœa of cholera, and before systemic poisoning has set in.

THE SURGICAL TREATMENT OF URETERAL WOUNDS.

There are but few reported cases of uncomplicated wounds of the ureters, though one or both of these ducts have not unfrequently been injured in abdominal operations on the ovaries, uterus, or vagina, GUSSEROW and other authorities stating that this accident has happened to most surgeons that have frequently performed vaginal hysterectomy; and traumatism during parturition has been the most frequent cause of uretero-vaginal or uretero-uterine fistula.

DR. F. KAMMERER published in the *New York Medical Journal* for July 2, a contribution to the treatment of ureteral fistula, in which he reported two cases of uretero-abdominal fistula caused by difficult abdominal operations, in each of which he subsequently successfully performed nephrectomy. The latter operation, first performed by SIMON for the cure of ureteral fistula, has been performed about an equal number of times for the cure of uretero-abdominal and uretero-vaginal or uretero-uterine fistula. Of the thirteen recorded cases of nephrectomy for ureteral fistula collected by KAMMERER, only two resulted fatally; one death being due to insufficiency of the remaining kidney.

When the ureter has been divided by a stab or gunshot wound, or accidentally in an operation, what should the surgeon do? In the recently published *American Text-book of Surgery*, the authors recommend that the divided or torn end should be brought to the surface of the loin or of the vagina and sutured there. This would probably entail a subsequent nephrectomy, an operation that these authorities countenance by referring to it as the measure for cure of the fistula, although they do not recommend its immediate performance so as to prevent the formation of a fistula.

Transplantation of the end of the ureter to the abdominal wall is not a simple operation, and KAMMERER proposed sometime ago that the renal end of the ureter should be ligated or secured by forceps. He has since withdrawn his recommendation of a ligature, because GUYON's experiments have demonstrated that, even under ordinary conditions, it will produce the symptoms of renal retention; the ligature causing by its firm constriction of the ureter the same reflexes that an impacted ureteral calculus occasionally excites. Closure of the renal end of the ureter by forceps, with an iodoform gauze tampon thereabout, would permit the removal of the forceps in the event of renal symptoms developing; and if the tampon had not excited adhesions that completely shut off the peritoneal cavity, any leakage of urine would tend to the surface by means of the tampon.

Instead of transplanting the ureters to the loin or vagina, DR. R. HARVEY REED has suggested in the *Annals of Surgery* for September, that in injuries of the ureters in consequence of ovarian or other neoplastic adhesions, or in case of disease of the bladder, the ureters should be implanted in the rectum. He has made some interesting experiments on animals to determine the feasibility of this procedure, and his experiments show that the unilateral implantation of the ureter into the rectum was a possible and practical surgical procedure, though bilateral implantation always terminated fatally in the animals experimented on. He found that the rectum readily accommodated itself to the presence of urine, and that the stools were, not necessarily liquid or frequent. He believed that the experiments showed that it was a safer plan to implant a ureter than to perform nephrectomy. This operation has yet to be performed on the human subject, though DR. REED's results commend it in preference to lumbar or vaginal implantation of the ureters, and it possesses the additional desirability of dispensing with a subsequent nephrectomy.

While nephrectomy has been immediately and successfully performed in such cases of ureteral ininjury, still such an additional operation is not without risk when a patient has just been subjected to the shock of a capital abdominal operation. And as DR. KAMMERER very pertinently suggests, while the increased demands upon the remaining kidney during the days following nephrectomy may be easily responded to when no other complication is present, they might prove too great when the patient is already struggling against the shock consequent upon a severe and protracted laparotomy. Furthermore, the operation of nephrectomy is far from being one of the most favorable procedures in surgery; though the condition of both kidneys may be ascertained to an extent at the laparotomy during which the ureter is injured.

The improbability of securing immediate union in a severed ureter in which there is no loss of ureteral tissue, would make the risk of intra-peritoneal extravasation of urine too great to attempt to suture the severed ends of that duct.

For the reasons above mentioned it may be concluded that in wounds of the ureter complicating abdominal operations immediate nephrectomy is undesirable, although its performance is not unjustifiable in traumatic injuries of the ureter *per se.*

That while the lumbar or vaginal implantation of the ureter has been successfully performed, secondary nephrectomy has often been resorted to for the cure of the troublesome ureteral fistula. And that the successful implantation of the severed ureter into the rectum, offers a measure that avoids the inconveniences and dangers of each of the foregoing procedures.

"PYOSALPINX."

"Pelvic cellulitis" existed theoretically, based upon purely clinical phenomena, and the term has almost disappeared from the modern nomenclature of disease, while the condition so long described as such has at last received its proper place in surgical science.

That pelvic cellulitis may occur cannot be denied, but that it is rare, even as a result of post-puerperal infection, has been proved by hundreds of accurate observations, both at the operating table and by post-mortem examinations. The classical essays of BERNUTZ and GOUPIL lay long forgotten under the rubbish of dogmatic and incorrect teaching, until the master mind of LAWSON TAIT, aided in Germany by HEGAR and MARTIN, and in America by JOSEPH PRICE, forced the attention of the profession to the exact pathology upon which "pyosalpinx" is founded. It is fortunate for the peace of mind of the common sense practitioner that his imagination is no longer taxed with a mysterious cellular absorption, for he can now readily understand an infection of a septic, gonorrhœal or tubercular nature, traveling by continuity of tissue from the endometrium to the tube, and too frequently he has had reason to regret a careless interference with the aseptic uterine cavity.

Nature in her effort at self-protection employs here, as with foreign bodies generally, a combination of the three methods, absorption, encapsulation and extrusion, and while she may be more or less successful in her effort, too frequently the result is disastrous to the life or health of the patient. Absorption and resolution of a mild infection of the tube without the formation of a pyosalpinx may take place, but often destroys the ciliated epithelium, thus rendering possible a future ectopic pregnancy. An encapsulation of the pus in the tube forms a pyosalpinx which is a source of constant danger through recurring attacks of pelvic peritonitis, or a possible perforation into the free peritoneal cavity. If unilateral, and pregnancy occur, the abscess may be ruptured during parturition, causing a fatal puerperal fever.

Extrusion of this pus by means of adhesions to the bowels and intestinal opening, either spontaneous or by the surgeon's knife, is usually an unfortunate occurrence through the resulting fecal contamination and inefficient drainage, while vaginal or more superficial openings may leave a suppurating stump of an ovary and tube which, like a sequestrum of necrosis in an involucrum of healthy bone, keeps up a chronic discharge and undermines the health of the victim. These undeniable facts lead to but one conclusion, that the early and complete removal of a pus tube by cœliotomy is surely indicated. The mortality of Joseph Price of less than 3 per cent. in his magnificent work is, however, almost unique, and the average death-rate, as given by McLaren, of St. Paul, in a recent paper, is about 9 per cent. in the hands of experienced operators. The plea for conservative treatment then, from the standpoint of immediate mortality of the operation itself, rather than the sentimental one so frequently advanced as to the removal of a useless and dangerous organ, is worthy of the utmost attention. The claim of electricity depends upon a basis of inaccurate diagnosis. Vaginal puncture is a blind and uncertain procedure, and as a pus tube frequently contains two or three complete strictures separating it into several pockets, the chance of emptying them all is small at best. The new treatment of curetting and iodoform gauze pack of the uterus, so useful in an endometritis, is an exceedingly insecure method of treatment in pyosalpinx. A very small number of well authenticated cases in which a pyosalpinx or cystic tube has been emptied into the uterus, cannot counterbalance the danger of such operative interference. The large majority of reports in which there has been a supposed uterine drainage of a pus tube, have been shown by J. Bland Sutton to be merely the discharge of retained uterine secretions, and in any event, the benefit of, such practice is probably not greater than follows free purgation. Any operation which opens the abdomen and then does not remove the pyosalpinx does not deserve the name of conservative, and is not good surgery, whether done by stitching the tube to the incision, or the late recommendation of the French to make a vaginal hysterectomy and leave the pus tubes to drain.

RAILWAY SURGERY AT THE PAN-AMERICAN MEDICAL CONGRESS.

A Section of Railway Surgery of the Pan-American Medical Congress has been organized with Dr. C. W. P. Brock, of Richmond, Virginia, as Executive President. A full list of officers has been provided for each of the constituent countries. At the Eleventh Annual Meeting of the Wabash Railway Surgical Association—the first organization of the kind—Dr. C. B. Stemen, of Fort Wayne, was by unanimous resolution, requested to prepare a paper on "Organized Railway Surgery," and read the same before the Section on Railway Surgery of the Pan-American Medical Congress. At the same meeting Dr. Hal C. Wyman, of Detroit, offered the following, which was unanimously adopted:

Resolved, That each member of this Association solicit his Congressman to interest himself in legislation in favor of the Pan-American Medical Congress.

The Samuel D. Gross Prize, Philadelphia Academy of Surgery.—The first quinquennial prize of one thousand dollars, under the will of the late Samuel D. Gross, M.D., will be awarded in 1893. The conditions annexed by the testator are that the prize "shall be awarded every five years to the writer of the best original essay, not exceeding one hundred and fifty printed pages, octavo, in length, illustrative of some subject in Surgical Pathology or Surgical Practice, founded upon original investigations, the candidates for the prize to be American citizens." It is expressly stipulated that the successful competitor shall publish his essay in book form, and that he shall deposit one copy of the work in the Samuel D. Gross Library of the Philadelphia Academy of Surgery. The essays, which must be written in the English language, should be sent to Dr. J. Ewing Mears, 1429 Walnut St., Philadelphia, before June 1, 1893. Each essay must be distinguished by a motto, and accompanied by a sealed envelope bearing the same motto, and containing the name and address of the writer. No envelope will be opened except that which contains the successful essay. The committee will return the unsuccessful essays if reclaimed by their respective writers, or their agents, within one year. The committee reserves the right to make no award if the essays submitted are not considered worthy of the prize.

SELECTIONS.

Biologic Therapeutics.—Medicine has entered upon a new era in therapeutics, which may appropriately be designated biologic. The scientific world greeted with cordial admiration the synthetic products of the chemist's skill, but we stand to-day on the threshold of developments the magnitude of which is beyond comprehension. Since the birth of the young science of bacteriology practical minds have assumed an expectant attitude. Skepticism has largely given way to confidence, and excessive enthusiasm to a calmer judgment. It soon became apparent, in a manner and to a degree in which it had never been before, that many diseases carried with them the elements of their own cure. Of course, it had been recognized that certain diseases are self-limited, and the phenomena of natural and acquired immunity were duly appreciated; but it required the knowledge gained by the advances in bacteriology to afford a rational explanation of these various phenomena. There is yet much to learn. The beginning has but been made. Enough, however, has been seen to teach that disease has its chemistry, and that the treatment of the future will depend upon a knowledge of this fact and the application of chemic laws. It is not too much to hope that the treatment of the future will largely be specific, that is, in the employment of a definite remedy in the treatment of a given affection, just as mercury and iodine are to-day employed in the treatment of syphilis, quinine in the treatment of malarial disease, and salicylic acid in the treatment of rheumatism. The groundwork of this new system of therapy has been already laid by Pasteur as to hydrophobia, by Koch in regard to tuberculosis, by Behring, Kitasato, Wasserman, and Ehrlich as to diphtheria, by Tizzoni, Centanni, and Cattani as to tetanus, by the Klemrerers as to pneumonia, by Ferran, Haffkine, and Klemperer as to cholera.

Stern (*Drutsche medicin. Wochenschr.*, 1892, No. 37, p. 827) has made an interesting contribution to this subject. He had previously demonstrated that human blood-serum possesses the property of destroying the bacilli of typhoid fever, He now endeavored to determine if the bactericidal activity of the blood-serum to the bacillus of typhoid fever is increased in persons that had recovered from an attack of that disease; if the blood of such persons had any curative action upon animals inoculated with the bacilli of typhoid fever; and if this blood has the property of neutralizing the poisons generated by the bacilli of typhoid fever. Seven cases were examined, six at intervals of from five days to five and a half weeks after defervescence had set in, and one, who was under treatment for sciatica, seventeen and a half years after an attack of typhoid fever. It was found that the bactericidal activity of the blood-serum to the bacilli of typhoid fever was distinctly diminished in persons recently convalescent from typhoid fever, in comparison with the conditions present in persons that had never had typhoid fever. It was further found that, while the serum of a healthy person exerted no modifying influence upon the toxicity of boullion-cultures of the bacilli of typhoid fever with which it was mixed, the serum of persons recently convalescent from typhoid fever exerted a distinctly modifying effect of an attenuating character. It was also demonstrated that a filtered extract of sterilized cultures of the bacilli of typhoid fever could be safely injected in doses otherwise lethal, if previously admixed with the blood-serum of persons recently convalescent from typhoid fever.

From the foregoing it is clear that the protective influence of the blood-serum of persons recently convalescent from typhoid fever is not dependent upon a destructive action upon the bacilli themselves. It will not do, however, at once to jump to the conclusion that the serum neutralizes the toxic products of the bacilli. It is also possible that the serum renders the animal organism less susceptible to the influence of the toxic products. This doubt would be removed if it were shown that the diminution in the toxicity of a mixture of the serum and the sterilized extract were progressive.

The observations here recorded are most interesting, and are deserving of thoughtful consideration. They should be repeated and extended. They seem to bring us nearer to a correct conception of natural immunity and natural cure. —*Medical News.*

Why we Should Have a Medical Officer in the President's Cabinet.—During the recent assault made upon the Atlantic fortifications of the great United States, the country was in danger of utter destruction, and every individual in peril of his life on account of the clash of authority which occurred between the federal and city authorities. Fortunately the federal officers gained the day, and great credit is due to them as well as to the Health Officer of New York City in keeping out the merciless foe of mankind. Although cholera entered New York, it can scarcely be said to have gained a foothold, and yet we shall await anxiously the developments of the coming spring, as it is now conclusively shown that cholera germs may lie dormant for months, and reappear under favorable climatic and filth influences.

But why have a repetition of so unseemly a disagreement? Why endanger the lives of sixty-fixe millions of people by a clash of any sort? Why not establish a medical cabinet officer as other civilized nations have, who shall have supreme authority in all such matters? We can see no more valid objection to a Minister of Public Health than we do to a Secretary of State or a Secretary of the Navy, for are not our commercial interests the lives of millions, as well as our very existence threatened on such critical occasions as we recently witnessed in New York harbor? Why, therefore, should we not urge our claims of protection from a foe more deadly than the invading Britons. By all means, let us have a medical officer of public health in the cabinet. Let him be well provided with a small army of medical men to guard us against further invasions. The health of our nation should be of supreme importance. It is estimated that the monetary loss to New York City alone by the present visitation of cholera was over 2,000,000 dollars! This fact alone should be sufficient to call the attention of our law-makers in Washington to the importance of the subject. Let us hope the matter will receive the attention of our next Congress. Surely no measure of greater importance can be introduced.—*Pacific Medical Journal.*

MISCELLANY.

Wanted.—Will pay 10 cents per copy for the following numbers of The Journal: Vol. 2, No. 4, Jan. 26; No. 19, May 2, 1884. Vol. 5, No. 2, July 11; No. 3, July 18, 1885. Vol. 6, No. 6, Feb. 6, 1886. Vol. 3, No. 4, July 26, 1884. Vol. 4, No. 22, May 30, 1885; No. 23, June 7, 1885; No. 24, June 14, 1885; No. 25, June 21, 1885; No. 26, June 28, 1885. Also, Vol. 12, No. 3, Jan. 12, 1889.. Vol. 12, No. 3, Jan. 19, 1891.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from November 12, 1892, to November 18, 1892.

First Lieut. Henry R. Stiles, Asst. Surgeon (recently appointed), is assigned to duty at Jefferson Bks., Mo.

First Lieut. Paul F. Straub, Asst. Surgeon (recently appointed), is assigned to duty at Ft. Riley, Kan.

First Lieut. Francis A. Winter, Asst. Surgeon, is relieved from duty at Ft. Riley, Kan., and is assigned to duty at Ft. Wingate, N. M.

First Lieut. A. E. Bradley, Asst. Surgeon, is relieved from duty as attending surgeon, Hdqrs. Dept. of the Platte, Omaha, Neb., and is assigned to duty at Ft. Sully, S. Dak.

Capt. Benjamin Munday, Asst. Surgeon, is relieved from duty at Ft. Sully, S. Dak., and is assigned to duty at Ft. Niobrara, Neb.

First Lieut. Harry M. Hallock, Asst. Surgeon (recently appointed), is assigned to Ft. McPherson, Ga., for duty at that post.

First Lieut. Robert S. Woodson, Asst. Surgeon, is relieved from duty at Ft. McPherson, Ga., and is assigned to duty at Ft. Barrancas, Fla.

First Lieut. George J. Newgarden, Asst. Surgeon (recently appointed), is assigned to duty at Ft. Sheridan, Ill.

First Lieut. Charles F. Kieffer, Asst. Surgeon, is relieved from duty at Ft. Sheridan, Ill., and assigned to duty at Ft. Meade, S. Dak.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Week Ending November 19, 1892.

Asst. Surgeon Geo. T. Smith, from Coast Survey Str. "Hassler," and to the "Vermont."

P. A. Surgeon C. H. T. Lowndes, from the U. S. receiving ship "Vermont," and to the "Hassler."

P. A. Surgeon W. F. Arnold, to hold himself in readiness for orders to the U. S. S. "Monterey."

P. A. Surgeon H. N. T. Harris, to hold himself in readiness for orders to the U. S. S. "Bancroft."

Surgeon G. F. Winslow, to hold himself in readiness for orders to the U. S. S. "Monterey."

ORIGINAL ARTICLES.

THE U. S. ARMY RATION AND MILITARY FOOD.

Read in the Section of Physiology and Dietetics at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY CAPT. CHARLES E. WOODRUFF, M.D.,
ASSISTANT SURGEON U. S. ARMY.

Col. Jos. R. Smith, Surgeon U. S. Army, read before the Ninth International Medical Congress, a paper on "The best Ration for the Soldier," in which he very carefully analyzed the ration then existing, compared it with the rations of foreign armies and the dietaries of various laborers, and discussed various other points. To go into this matter again would be threshing out old straw, and the present paper therefore is confined to a description and discussion of the present ration which has been somewhat modified in form and considerably modified as to its management since the time at which the former paper was written.

An army is a collection of disciplined, active, healthy men in the prime of life, to be used as a fighting force in the service of the nation, and it is the object of military administration to so govern and train these men that they shall not fail when fighters are needed. Everything is to be done which can reasonably be expected to increase their efficiency, and it is an actual fact that nearly every military law and regulation has for its ultimate effect the increased efficiency of the individual soldier as a fighter. Unless the man is kept in health, he is useless, and for this reason all subjects which relate to his health are given much thought. Clothing, food, shelter and exercise are the principal subjects for consideration for if any of them are improper, there is sure to be a loss of efficiency, but it is probable that deficiencies of food or improper food will cause damage or disaster more quickly than anything else. For instance, most of the diseases of the war of 1812 were due to defective food, and in ninety per cent. of the cases the flour was at fault. In the war of the rebellion similar reports were often received, and the tales of actual hunger that all veterans recount, are too numerous by far. It is evident, therefore, that the ration should be the subject of most careful thought, and all reasonable means be tried to adjust it to the exigencies of military life.

A "ration" is the technical term for the sum total of the daily allowances of food issued to the soldier in accordance with law. Its present constituents are given in full in tabular form below.

The candles and soap are considered a part of a ration, though not food.

MANAGEMENT OF RATION.

It must not be thought that the soldier is restricted to the actual articles that are mentioned in the table, for by a fairly efficient system, the company commander is permitted to make outside purchases of food. If there is any excess of food uncooked which will not be used by the company, he sells back to the commissary the excess, technically called the "savings," and with the proceeds buys what he thinks proper. These savings are a very important matter, and amount in the aggregate to a fair sum per company, although per man they may average but from 1 to 4 cents per day. This fund is still further augmented by the receipts from the Post Exchange; this institution is a general store for the sale to soldiers of small articles he may need, such as stationery, tobacco, lunches, beer, etc., the prices being a slight increase over the cost, and the net profits being turned into the company funds—in other words, a coöperative retail store which makes each soldier a silent partner, though not subject to any losses.

TABLE I.—U. S. ARMY RATION.

Component.	One Article of Each List.	
Meat	12 oz. pork 12 oz. bacon 22 oz. salt beef 20 oz. fresh beef 20 oz. mutton 14 oz. dried fish 18 oz. pickled fish 18 oz. fresh fish	In 10 days it is usual to give 7 days' of fresh beef, 2 of bacon and 1 of salt pork. The other articles are very seldom issued.
Bread . . .	18 oz. flour 18 oz. soft bread 16 oz. hard bread 20 oz. corn meal.	Soft bread is the invariable issue in garrison.
Dried Vegetables . . .	2 2-5 oz. beans or peas. 1 3-5 oz. rice or hominy.	
Fresh Vegetables . . .	1 lb. potatoes or 9-10 potatoes and 1-10 onions or 8-10 potatoes and 2-10 onions or 7-10 potatoes and 3-10 canned tomatoes 7-10 potatoes and 3-10 vegetables, such as cabbage, beets, carrots, turnips, squash, etc.	
Coffee . . .	1 3-5 oz. green coffee. 1 7-25 oz. roasted coffee. 8-25 oz. tea.	
Sugar	2 2-5 oz. sugar. 16-25 gill molasses or syrup.	
Condiments and additional articles	8-25 gill vinegar. 16-25 oz. salt. 1-25 oz. pepper. 6-25 oz. candles. [In the field.] 16-25 oz. soap.	

During the first three months of 1892, the average daily receipts and expenditures per man at Fort Assinniboine, Montana, were as follows:

From ration	2.72	cents.
From exchange	2.58	cents.
From other sources	.34	cents.
Total receipts	5.64	cents.
Expenditures for extra food	4.11	cents.

It will be noticed that the profits from the Post Exchange enabled the daily average expenditures for food to exceed the savings from the ration by 1.39 cents per man. These figures are the averages of nine companies and troops, each having about fifty men.

It is forbidden company commanders to use the savings from the ration except for the benefit of the soldier's table fare, so that there shall be no cheese-paring of the ration in order to save money for other purposes. Very recently part of the savings of the ration was turned into post, band, regimental funds, and what not, and the money used for objects from which the soldier derived no food benefit whatever. It is a curious thing that when in 1864 it was discovered that the soldier could not eat all of his ration, which had been increased in 1861, and that the savings went into post and regimental funds, it apparently did not occur to anyone to abolish these funds, but instead it was deemed wise to reduce the ration to what it had been previous to 1861, notwithstanding the fact that the soldier was often underfed. It was over 25 years before this setback was remedied. At present then, if, owing to climate or other causes, the soldier does not want all of the food to which he is entitled, the money savings must either accumulate in large amounts or be used for the purchase of those little extras, which, added to the bare needs of existence, make life much more worth living. In addition it must be said that large company funds are, as a rule, frowned upon, and, other things being equal, the officer who allows the money to accumulate instead of spending it judiciously for the benefit of his men is not considered to be doing the best. As a general rule it may be safe to say that when a company is so situated as to be liable to be called suddenly into the field, its commander considers it wise to accumulate and keep on hand a certain fund of from $200 to $500 for the purchase of extras in the field whenever practicable, for to be compelled to subsist on the plain ration is looked upon as a misfortune. To keep on hand a fund of one to two thousand dollars is not considered wise management.

In drawing beef at the larger posts, the contractor usually supplies a fore quarter and a hind quarter alternately. At those posts on the frontier where forage is very scarce, the beef is necessarily somewhat tougher than it would be if the cattle could be properly fed before killing. The allowance (1¼ pounds) is gross weight, the actual amount of meat is much less.

It rests with the Department Commander usually as to how much of each kind of article the soldier shall have when the law allows a choice. It is perhaps usual to order that in ten days there shall be seven issues of beef, two of bacon and one of pork, but if the soldier can with the help of outside purchases, manage to subsist for ten days on the beef allowed for seven days, he saves the money value of one day's pork ration and two of bacon. It might be added that "savings" of fresh beef and fresh vegetables are not permitted, the company being compelled to draw all their allowance, though this regulation does not forbid them to sell privately any they have drawn and which will not be used, but become spoiled by decay.

The management of the flour is taken out of the hands of the company commanders entirely and all flour turned into the post bakery, where all the bread used by the men is baked. The ration of flour is 18 oz., and the soldier is entitled to either that or 18 oz. soft bread, but as that amount of bread can be made from about 10 to 14 oz. flour, there is a large saving of flour, which is sold and after deducting expenses of the bakery, the surplus is returned to the company. Flour needed in the companies for puddings, griddle cakes, and the like, must be purchased from the company fund. There is usually a good baker among the soldiers at each post or several men who have an aptitude for that trade and who easily learn. These men are detailed for the bakery work and receive extra pay. With but rare exceptions the bread supplied to the soldier is excellent.

By means of the above system of management, a company fund is kept from which the extra diet on holidays can be purchased when there is a convenient market, as for instance turkey on Thanksgiving and Christmas, eggs on Easter and so on. At all other times the fund is constantly drawn upon for the purchase of extras. This fund is considered of the highest importance, and new restrictions are being constantly thrown around it to prevent savings from the ration being diverted to other purposes than for the increased efficiency of the soldier's table. The existence of a good fund for the purchase of extras, has always been taken for granted. An army cook book is issued to troops, and it is full of useful and excellent recipes, but 75 per cent. of them call for articles not supplied in the ration, such as butter, lard, eggs, flavoring and seasoning, and the unfortunate company that is minus a company fund can find no use whatever for over half of these recipes.

The ration is designed for healthy men, and admits of no flexibility to suit the sick. For the latter who might die if forced to subsist on the harsh components of the ration, another arrangement is made. The ration of the sick, or its money value, is given to the surgeon who buys the extra diet that is needed, which purchases are further increased by such articles as beef extracts, condensed milk, etc., supplied by the Medical Department for the use of the sick only.

SELECTION OF RATION.

An army must often be fed at a great distance from the market, and it is therefore evident that the chief objects in view in the selection of the soldier's food must be facility of transportation and ease of preservation in all climates. Articles that are bulky or easily damaged by rough handling, and those that are not easily preserved from decay are at once ruled out. It need scarcely be mentioned that the articles must be produced in abundance throughout the country, neither imported nor the particular prepations of a few manufacturers. Couple with this, the fact that the articles must be so inexpensive as to refute any charges of extravagance and it will be readily understood that with a few exceptions, the the ration contains about all the articles that it is possible to put in it at present without calling on foods that are preserved, canned or otherwise specially prepared. In regard to charges of extravagance it may be remarked in passing, that as the present ration usually costs less than 15 cents it is rather far fetched to talk of extravagance. There are few healthy laborers in respectable standing in civil life who subsist on less than one dollar a week.

For these reasons, the soldier's ration has always been simple and dry. Indeed, until quite recently, there has been but little change in the ration for 75 years. For instance, omitting details, during the revolution, the soldier's food was essentially: 1 pound beef, 1 pound bread, 1 pint milk, 1 quart beer, and a taste of molasses and dried vegetables, though practically he received but a small fraction of his allowance. In 1785, after the war, it was even simpler, 1 pound beef, 1 pound bread, and 1 gill of rum. The beef was increased to 1¼ pound in 1798, and the bread or flour to 18 oz. at the same time, at which they have since remained except for three years during the rebellion when the bread or flour was increased by four ounces. At this time also (1861–1864) 1 pound potatoes was issued three times a week. From time to time other changes and slight additions were made; in 1818 some dried vegetables (peas, etc.,) were added; in 1832 a small amount of coffee and sugar was issued in lieu of spirits, and there have been numerous changes in salt, pepper and vinegar. The coffee and sugar have remained unaltered for 32 years. At the present time the ration is more liberal than it has ever been before.

Human beings can by degrees become accustomed to any diet, even though it be outrageous; they can subsist chiefly on fruits in the tropics or chiefly on fats in the arctic regions, but any rapid change of diet is disastrous. Now, as the militia when mustered into the service of the United States must subsist on the army ration, it is a cardinal principle that the food supplied must closely approximate that to which they are accustomed. As regards the present ration this is approximately so, but it has not always been the case. The Secretary of War (Mr. Calhoun) in 1818 reported to Congress that the mortality during the wars of the revolution and 1812 from the change of a plentiful mode of living to that of the camp, "was probably greater than from the sword." As Americans live more liberally than Europeans in similar walks of life, we have at once an incontrovertible reason why the U. S. ration should be more liberal than that of any European army. The American laborer has meat every day, while the European laborer may have it but once a week, and the American soldier must and does have meat three times a day.

There is another point to which a mere reference is necessary. In cold climates no article can be used in the field in winter, that would be spoiled by freezing, or by alternate freezing and thawing. This blocks out a few articles put up in cans in fluid preservative, potatoes and all fresh vegetables, and fruits and various other articles.

Until quite recently (within 50 years), it was presumed that if the ration kept the soldier alive it was sufficient. The idea that it should keep him in health is modern, and logically follows both from increased knowledge of the etiology of faulty food in the production of disease, and from a contemplation of disastrous epidemics on land and sea, following upon a long continued improper food. The smallest amount of food that will keep a man alive has been approximately known for centuries, and though modern experiments make our knowledge vastly more detailed, accurate, and scientific, they have added little to the knowledge that one pound of bread and 1¼ meat daily will subsist a man for quite a long period. When we come to discuss the amount and kind of food necessary to keep him in health we are on debatable ground. Our knowledge on this subject is not yet complete enough, we have only theories and opinions. A man may appear to be healthy, but it is not quite certain that he may, on the one hand be taking too much of one variety of food, generating a tendency to plethora or lithæmia, or on the other hand living in a constant tendency to anæmia or scrobutus, with all the liability to contract other diseases from lessened general vitality and resisting powers. We all know men whose usual daily food is even more simple than the ration, but we know also that there are times, as during occasional visits from home, when they eat other things that perhaps restore the balance. Patients have often been restored to health by a change of diet made necessary by a recommended change of scene.

VARIETY.

The soldier is occasionally so situated for prolonged periods that he leads an essentially sedentary life, and the total amount of food energy needed is far less than what is supplied. It is in such circumstances that there must be more variety than the ration affords. When he works hard he can subsist on an unvaried diet and feel well, but if he lives in enforced idleness, the poorer menu seen in table 12 would soon cause satiety. Practically and usually, variety is secured by purchase or gardens, but occasionally it cannot be so secured. The gardens at military posts are considered of great value and fostered with as much care as possible. Seeds and implements are furnished to a certain extent, suitable ground reserved for the purpose, and men detailed for the work and excused from other duties. There is a feeling that the soldier should not be compelled to raise his own vegetables. The company is liable, in some places, to be called into the field and the garden neglected to its ruin, and the daily military routine with its exactions and privations is liable to discourage in the soldier such continuous labor as is the lot of farmers. Practically it is found that there are several men in each company who have been raised as farmers, and who are anxious to do the work.

The diet can be greatly improved by the addition of soups, providing the cook is efficient. Bones are too often thrown away, and though they cannot supply much nutriment, as explained on page 659, yet soups may be made the vehicle for the nutriment of rice, beans, tomatoes and other vegetables. Those companies blessed with good, economical, and energetic cooks usually have soups quite frequently, and the extra comfort thereby gained more than compensates for the trouble.

In regard to the variety of the ration, the thought is now being evolved that it is no more necessary to have a ration that will keep in all climates, than it is to have a uniform that can be worn in all climates, whether 50 below zero, or 130 above. As the food can be purchased within the climatic district in which it is used, the ration in the extreme north can be of such a nature that it might spoil in the extreme south or *vice versa*. If such a radical idea ever becomes practicable it will greatly facilitate the process of making the ration flexible. A few years ago it was thought that the soldier of the southern summer must eat the same kind of fat pork, etc., that was used in the northern winter, but at present it is recognized that there must be a distinction, and as time goes on there is a greater and greater tendency shown to adapt the food to the place and circumstances. The addition to the ration of fresh vegetables in 1890, has been one of the greatest advances made since 1818, when dried vegetables were added in lieu of some of the old issues, and various other substitutions permitted. The occasional issue of dried or fresh fruits of the cheaper and more easily preserved varieties would be a boon highly appreciated by the troops in the hot districts of the south.

If two ships were to start from New York, each to be absent several years, one in the Arctic regions and the other in the tropics, no one would even dream of provisioning them alike. Yet if two armies were similarly to start from New York for long periods, one to the extreme north, and the other to the hottest parts of the south, the law presumes that both shall carry essentially the *same* rations. We have not yet reached the point where it is decidedly recognized that the variety in the ration must be great enough to permit of sufficient flexibility to suit extremes of climate.

As all armies in the world have been fed on the same general principles, there is scarcely any doubt that the dryness and the sameness of the food is a great factor in the production of the tendency to drunkenness, proverbial among soldiers and sailors. Drunkenness can never be eradicated from an army. The class of men from whom the soldiers are recruited are not tee-totalers, but it is safe to say that there has been a phenomenal decrease in the amount of drunkenness in recent years, and it may be justifiable to predict a still further decrease as the food becomes more varied. The writer once canvassed the men at a small post, Fort Gaston, California, and found that there was a large per cent. of total abstainers, and at that time, he was certain that it was a larger percentage than among mechanics and laborers in civil life; but the post was most favorably situated, was blessed with an enormous garden for vegetables, there was a profusion of fruit in season, and game could be obtained throughout the year. As elsewhere mentioned, the sameness of diet of German soldiers during the Franco-Prussian war when Ebswurst was used, was compensated for by the large stores of wine found in the vicinity of Paris, and by the occasional issue of brandy, a still further proof of the tendency to drink alcoholic beverages when food is scanty and unvaried.

It is probably true that at posts in cold climates in winter when there is much idleness, and the diet is not varied, the soldiers suffer more from chronic constipation than an equal number of healthy civilians. It would be impossible to substantiate such a statement because reference is made to those slight cases which never appear on the sick report, but who try to treat themselves with patent medicines. If it is true generally, it is due in part at least to the sameness of diet and the absence of fresh fruits and vegetables. Since the addition of potatoes all the year, and of fresh vegetables in summer, there may have been an improvement, but how much, if any, is not known.

The enormous number of cases of rheumatism occurring during the rebellion and since the rebellion in veterans may not be entirely due to the exposures, as popularly supposed. These men were hardened to exposure and should not have had more rheumatism than hunters, trappers, and the aboriginal Indians. The limited, often insufficient, ration and the absence of fresh articles may have been one of the factors at work. Indeed, new facts are being continually brought forward, showing new relations between a disease and the habitual diet of a patient. Diet also in its relation to diseased states, is becoming an all important item of therapeutics. It may be justifiable therefore to express a doubt as to whether in the long run, the bare, unadorned unvaried ration as issued, will tend towards the production of perfect health and the greatest efficiency, if eaten to the exclusion of everything else.

COOKING.

Every soldier is supposed to be able to cook his own ration. He can no more do it than can every mechanic go into his own kitchen and prepare his own meals. Cooking is a fine art and cannot be learned, though some of its technique can be taught. There must be aptitude. Officers of experience state that unless the soldier shows much aptitude as a cook it is useless to try to teach him. In every company there is usually one man who is fairly expert, and he is detailed as company cook and excused from other duties. It is almost needless to remark that he is a most important adjunct of the military organization. It has been said that the cook is the real manager of a company, and as he is good or bad, so is the company good or bad. The writer once served at a post where one company, blessed with a born cook among its soldiers, lived in a state as nearly approaching luxury as could be desired, while another organization with exactly the same ration, but having a thorough-bred idiot for a cook, lived on miserable fare and were discontented and thoroughly unhappy. Indeed, if the soldier's ration were as good and varied as the country affords, it could be ruined by some of the men who preside over the army cooking. This matter has become so important, that it is now recommended on all sides that a special cook be enlisted for each organization as is the case in the navy. It may be said that the soldier is occasionally absent from his company and in that case should be able to cook his own ration, but in that case, he cannot carry utensils, and he is furnished with a special cooked ration to be described, and in addition the uncooked ration is supplied to the company only when cooking is practicable.

Though the frying pan is a recognized evil in civil life, wastes food by making much of it indigestible, causes dyspepsia and untold evils, and is a general all around nuisance to physicians, yet it is well nigh impossible to do without it in the army, particularly in the field. A trapper or frontiersman will cling to his frying pan as his dearest friend, and the soldier's fire indeed admits of only the simplest kind of cooking—frying and boiling. The evil in the field is not so great as would be supposed, for it is well known that outdoor life certainly increases the digestive powers to a most wonderful extent. The writer once knew an officer who was a confirmed, pessimistic dyspeptic, whose diet had to be almost as carefully selected as a child's, and whose illness was probably due to lack of exercise, for when he took the field and was compelled to do fatiguing work, he ate large quantities of fried food, dripping in grease, and not only was he comfortable, but he grew fat and was actually cheerful. In the garrison diet lists of tables 12 and 13 it will be noticed that there are very few fried articles.

At certain large posts an innovation in the way of a general mess is now in practical operation, the cooking is all done in a central kitchen and the men all partake of the same fare. This change is being tried in the interest of economy and efficiency, it being supposed that there is less waste and better cooking. It is possibly too soon to give a definite opinion as to the value of the general mess in the army. For field service, particularly in the western country, where a company is so often on duty detached from its regiment, the company mess will probably prevail, because the utensils must be kept on hand, and the system must be constantly practised in order to be efficient, and in addition it is not practicable with camp fires, and portable ovens to cook for very large numbers in temporary camps or on the march.

Very closely connected with cooking is the proper serving of food. When soldiers are in the field, each one must look after his own affairs and take care of his own tin plate and cup, iron knife, fork and spoon, and nothing breakable is carried. Everyone who has been camping knows how difficult it is to take along many appliances, and how makeshifts must be used when serving food. In garrison there has been a decided change in recent years. Each company formerly bought its own dining outfit which was very elaborate in some cases, but quite poor in others; at present all are supplied by the Quartermaster's Department with very fair utensils, plain white dishes, silverplated knives, forks, and spoons, etc. These utensils make the table look very well, and as scrupulous cleanliness is invariably the rule, the appearance of the soldier's dining room in general is conducive to good appetites. This great attention given to the dining room and serving of food has a very decided elevating effect upon men. In civil life unusual brutality in men is not infrequently accompanied by the grossest table manners, and each is cause and each is effect, reacting upon one another. Compel a man to observe decency at table, supplying him with a neat, clean and orderly outfit, and the elevating effect is sure to come. Military men of the last century believed that to keep a soldier up to a proper discipline he should be clothed roughly, given the simplest kind of overcrowded barracks, and fed like a hog, every modern improvement being considered enervating. Could any of these dead officers see the dining rooms of some of our soldier barracks, they would surely think that the service was going to the dogs. It has been elsewhere remarked that when hardships slowly reduce vitality, the man is made less able to exist under more privation in the field. When there are no luxuries and everything has to be plain in order to be durable and serviceable, it is utter nonsense to talk of the enervating effects of luxuries. The present policy of improving the soldier's table service certainly improves the ration on principals known to every physiologist. The companies where the table is still bad are becoming the exceptions to the rule.

GARRISON RATION.

In calculating the food value of the soldier's garrison ration it has usually been the custom to take the articles mentioned in the regulations. This ignores the food from outside purchases, often considerable, and does not show what the soldier actually eats. The writer has been at considerable pains to find out exactly how much the soldiers ate at Fort Assinniboine, Montana, during the ten days from March 11 to 20, 1892. There were supplied to each company, blank forms on which were entered the itemized amounts of food on hand at the beginning, received during the ten days, and on hand at the end, from which was calculated the amount eaten, due allowance having been made for waste which was also carefully measured. The results of these experiments are detailed in tabular form below. These figures are accurate within moderately small limits for the weighings were carefully done under the direction of the company commanders, and wherever it has been possible to verify the results by other determinations they agree. The results are of considerable interest because it is the first time this work has been done since the ration was increased by the addition of vegetables, since it has been forbidden company commanders to use the saving of the ration for other purposes than for the table, and since the fund for extras has been so largely increased by the profits of the Post Exchange. When it is considered that at this isolated post, outside purchases are limited, that the Exchange is scarcely yet in full swing and that the garden-truck had been already consumed, it can be readily imagined that under more favorable conditions the variety of food might be far better and that the amounts of alimentary principles somewhat different, perhaps larger.

TABLE II.—PERCENTAGE COMPOSITION OF EDIBLE PORTIONS GARRISON RATION.

	Water.	Protein.	Fats.	Carbo-Hydrates.	Salts.	Energy, calories per lb.	Authority.

Crackers	...	10.3	9.4	70.5	..	1900	Estimated from A.

L.—Letheby. A.—Atwater.

In table 2 there is stated merely for reference the percentage composition of the various articles consumed. Some of these values assumed for the articles are probably different from those used in making the experiments whose results are taken as a guide. In all cases there was an authoritative estimate on which to base the assumed values. As the percentages are averages, the results obtained by using them cannot be considered as precise or accurate but were approximations whose probable errors may be large.

TABLE III.—UNCOOKED FOOD OF GARRISON RATION FOR 10 DAYS. WEIGHTS IN POUNDS. DAILY AVERAGE, 440.4 MEN.

	Gross Weight.	Waste.	Net Weight.	Water.	Protein.	Fats.	Carbo-hydrates.	Salts.	Calories.
Bacon	273¾	3¾	270	54.00	21.60	187.65	. . . .	6.75	831,600

REMARKS ON TABLE III.

The amounts of beef were calculated as follows,—After deducting 993¼ pounds bone, and 37¾ pounds other wastes, the rest was considered as edible, and its composition calculated according to Atwater's percentages, but there was a further waste of about 100 pounds fats, and that amount was subsequently deducted from the amount of fats and its heat energy taken from the number of calorics.

There were 4,546 rations of bread used, amounting to 5,114¼ pounds of bread, a ration of bread being 18 ounces. From this is deducted 167¾ pounds of bread wasted, leaving the amount eaten, 4,946½ pounds of bread. During the month of March, 10,300 pounds of flour were used in the Post Bakery to make 13,669 pounds of bread, so that the 4,946½ pounds of bread eaten represents 3,727½ pounds of flour. The bread wasted *(167¾ pounds) contains 126½ pounds* of flour, so that the flour used was 3,854 pounds. To this is added 525 pounds flour purchased for other purposes, making the total flour used 4,379 pounds, and eaten 4,252½ pounds.

The bacon is estimated from the tables of Letheby, neither of the estimates there given can refer to the fat and smoked variety supplied to the soldier.

Everything below onions was purchased from the company funds and some of those above onions, that is, some beef, flour, potatoes, onions and sugar.

TABLE IV.—PERCENTAGE OF WASTES.

Bacon	1.40	
Pork	8.00	Only 9 lbs. were reported, but this was increased to 31 lbs., to include bones, etc.
Bread	3.30	Crusts and small unavoidable wastes.
Beef	22.50	*19¾ bone, 2¾ fat and other wastes.*
Potatoes	27.09	Parings and defective ones.
Onions	21.04	“ “ “
Prunes	33.00	Stones and other wastes.
Cabbage	45.00	
Ham	12.00	Estimated.

Table 4 needs scarcely any explanation, but attention might be called to a few facts. The bones of beef were weighed with great care, and the result 19¾ per cent. agrees almost exactly with Atwater's tables. The percentage of bone usually given (17) is too small. The law that states that the soldier is to get a ration of 20 ounces of beef has always been interpreted to mean gross weight, so that he gets but 15½ ounces edible meat, and as physiologists in referring to the army ration, imply that the food is essentially 1 pound bread and 1¼ bone free meat, there has always been a misapprehension. In Dr. Dalton's minimum diet of 19 ounces of bread, 16 ounces of beef, and 3½ ounces of fat, the meat is all edible. It is an open question whether there is any justification for considering the law as referring to bone-free beef; an overpowering spirit of generosity would suggest the latter.

In the case of potatoes there is a large waste, 27.09 per cent. which is what might be expected, so that there is really served to the soldier only 11 ounces instead of 16.

Onions have a waste of 21.04 per cent. which is apparently correct.

Bread, beef, potatoes and onions were very carefully determined. There were wastes in the following articles, but so small in amount that they have been ignored: beans, rice, macaroni, hash, dried apples.

Where there are efficient cooks, the kitchen waste contains nothing of any food value to the soldiers, and is thrown away as in civil life. Though it may have a value for fertilizer or for live stock, there is usually no market. It is often the custom for each company to keep hogs, but the surroundings are apt to get in such an unsanitary condition that the practice is usually abandoned on the score of health. The bones might be of value, particularly in this State, for the market value of bone dust is said to be sixty dollars a ton, and taking the local value of bones at thirty dollars, there is a loss of one thousand dollars a year at this post from the bones thrown away.

TABLE V.—ADDITIONAL ARTICLES CONSUMED.

	Daily per man.	Allowance.	
338 lbs. green coffee	1.23 oz.	1.60 oz. or	
8 lbs. tea	.03 oz.	.32 oz.	
20 gall. vinegar	.14 gill	.32 gill	Allowance is large, to allow of making a saving to be used in making sauerkraut and pickles in the fall.
128 lbs. salt	.46 oz.	.64 oz.	
10 lbs. pepper	.036 oz.	.04 oz.	
11 bottles flavoring extracts.			
3 lbs. mustard.			
24 lbs. baking powd'r			
6 lbs. currants.			
5 gall. pickles.			
4 kegs pickled pigs' feet	Though containing much energy, it is omitted because composition is unknown, and the actual amount per man is very small.		

Table 5 contains a list of articles which were supplied and consumed, but as they contain practically no nutriment, they have been omitted from table 3.

TABLE VI.—CONSUMPTION AND ALLOWANCE PER MAN.

	Daily per man.	Allowance.	
4,379 lbs. flour	15.91 oz.	18 oz.	Includes purchases.
4,946½ lbs. bread	17.97 oz.	18 oz.	
343¾ lbs. pork	1.34 oz.	1.2 oz.	
273¾ lbs. bacon	1.00 oz.	2.4 oz.	
5,025 lbs. beef	18.30 oz.	18.0 oz.	
5,116 lbs. potatoes	18.5 oz.	12.8 oz.	80% of vegetables.
700 lbs. onions	2.5 oz.	3.2 oz.	20% of "
428½ lbs. beans	1.5 oz.	2.4 oz.	
763 lbs. sugar	2.7 oz.	2.4 oz.	
64 lbs. butter	.2 oz.	.....	
137 lbs. lard	.5 oz.	.....	
15 gall. syrup	.4 gill	.....	

Table 6, giving the amounts used per man with the allowance of a few articles in table 3 is given merely to supplement the latter table and contains only the items used in the greater amounts.

The following articles were in greater quantities than the ration, the excess being purchase: Beef, potatoes, flour, and sugar. The savings were chiefly on flour (from bakery) and bacon. Almost all of the companies bought beef, potatoes, lard, syrup, and baking powder, and a few bought flour, butter and bread. The use of butter, lard or syrup bears out the ideas of certain officers that one of these articles should be an article of issue and not of purchase, on the supposition that the company fund should be used to purchase articles of occasional use and not articles of constant use. The expenditures for extra food during these ten days were larger than the average expenditures for the three months of January, February, and March. With rare exceptions the soldier uses more than his allowance of potatoes.

FOOD EATEN AT POST EXCHANGE.

Table 7 gives the itemized amounts of food eaten at the Post Exchange lunch counter during the ten days. The men who ate this food were, according to the officer in charge, wholly among the 440 men of the companies, the other soldiers at the Post who board themselves do not patronize this lunch counter. Some of the results are necessarily assumed for no authentic percentage tables of values are probably in existence, but each value was calculated from the tables of value of similar articles in Pavy's work on Foods. It is probable that the aggregate error is not large, as the articles referred to, canned oysters, shrimps, canned fruit, mince meat, etc., are in small amounts and besides do not contain much energy per pound.

TABLE VII.—AMOUNTS OF FOOD EATEN AT POST EXCHANGE.

20 oz. daily per man { Grams	3.	...	27	21	286

In the Post Exchange there were sold during the ten days, 3,744 bottles (quarts) of beer. The officer in charge reports that the 440 men of the companies whose food is being calculated, drank their proportional share, and as there was a daily average of 473 men present, it would give an average of 24 ounces per man. As some men drank while others did not, it is probable that a few of the former occasionally took more than they could assimilate and counting the undigested as waste, 20 ounces per man are therefore assumed as the daily average consumption, and this corresponds with the minimum allowed to a healthy man by Parkes, one to two pints of 20 ounces each. The percentage composition of this beer was furnished by the analyst of the brewing company and the calculated values are stated separately in order that he who does not believe that the small amount of alcohol and carbo-hydrates of beer can serve any useful purpose in the economy towards the production of energy, can omit the beer if he chooses. Alcohol being between fats and carbo-hydrates in heat production, is assumed to have heat value of 1½ times its weight of carbo-hydrates.

All other alcoholic beverages consumed during the same time are unknown, they cannot even be assumed, and as they add some energy to the sum total, the results given without them can be therefore very safely taken as below the actual alcohol used per man, rather than above it.

Thus the whole amount of food eaten in ten days by 440 healthy, active men in the prime of life, is known within a very few pounds. All sources of outside supply are absent, they can get food at no other places. There is a trader's store, but on inquiry it is stated that the amount of food purchased (crackers, cakes, candy, etc.) is so small that the daily average amount per man is probably less than a gram of each of the alimentary principles. For these reasons much care has been taken to calculate the proper values, in order to give as great an accuracy to the results obtained as is possible, while at the same time illustrating the actual food of the soldier. A word might be said as to the other conditions. The men during this time were fairly active, having daily drills, and fatigue duty, once a week gymastics, and large numbers patronizing the gymnasium and other sports during leisure hours. The weather was cold, averaging 24° F., ranging from 64° above zero to 1° below. It must be remembered that the results represent nothing more than stated, and as elsewhere explained there should be no attempt made to give these figures as the proper food values necessary to keep in health an active man in the prime of life and performing moderate labor. That this food appears to keep the men in health, cannot be denied for an instant.

THE RATION IN THE FIELD.

When troops are in a permanent camp close to markets, and cooking facilities are improvised, the ration may be essentially the same as that already described in garrison. When at a distance from markets and from the base of supplies, it is not so varied, for purchases are impossible and the food is absolutely limited to that which they have been able to carry with them in supply wagons. The ideas of different officers vary somewhat as to what are the best and most palatable articles for camping, but the following is the list from which choice is to be made.

TABLE VIII.—RATION IN THE FIELD.

Meat	12 oz. fat pork or 12 oz. fat bacon.
Bread	18 oz. flour or 16 oz. hard bread.
Vegetables	2 2-5 oz. beans or 2 2-5 oz. peas or 1 3-5 oz. rice or 1 3-5 oz. hominy.
Fresh vegetables	16 oz. potatoes (if they can be carried).
Coffee	1 3-5 oz. green coffee or 1 5-25 oz. roasted coffee or 8-25 oz. tea.
Sugar	2 2-5 oz. brown sugar.

If dried vegetables cannot be cooked, the money value thereof may be issued in meat or bread.

This amounts in alimentary principles to the following:

		Protein.	Fats	Carbo hydrates.	Calories.
Grams.	Maximum	106	320	540	5,166
	Minimum	64	240	460	4,722
Average		85	280	500	4,944

The detailed figures are not given, as the averages thus shown are sufficient for practical purposes of comparison. The most striking fact about this ration is the deficiency of protein. The fats are not in excess, considering the conditions of service, and the high rate of heat energy is due in great part to the fats of the pork or bacon. These facts are enlarged upon below.

RATION ON THE MARCH.

When on the march where good camps can be made every night and transportation facilities are abundant, the ration is the same as for the camp already described, but when the troops are compelled to march every day, certain changes may become necessary. The dried vegetables are in such small amounts that they do not alter the relative proportion of the various constituents, and they are omitted in the following discussion. If the country is well settled, fresh meat and vegetables may be procured by purchases from the company fund, but in the wilderness it is a choice between pork and bacon. For its convenience in frying, bacon is usually carried. Pork is not so convenient but by the following method is said to be preferable. Capt. W. F. Spurgin, 21st Infantry, a recognized authority on the ration, writes that during the Nez Perces campaign in 1877, when the troops were following the Indians hundreds of miles, he would on making camp, start a fire and have the pork thoroughly boiled; this was put away to cool and be used during the next day. At the same time some soup stock, which was carried along, was quickly made into a good soup for dinner. Whenever it was convenient and bones could be secured, enough soup stock was made by prolonged boiling to last several days. Beans were also prepared by cooking them over night.

The hard bread (16 ounces) and flour (18 ounces) do not differ much in their ultimate composition and it is immaterial which shall be carried. When the camps are convenient enough, some form of biscuits can be made with the yeast powder supplied, and in such circumstances flour is taken.

In regard to the nutriment contained, it *is* material whether pork or bacon be used. The fat salt pork contains but a small amount of protein (.9 per cent.) and a large proportion of fat, probably 85 per cent.; the bacon contains far more protein and less fat, but the actual percentage composition has not been experimentally determined. The analysis of bacon by Letheby (8.8 protein and 73.3 fat) refers evidently to dried breakfast bacon; the soldier's bacon contains less meat and more water and is therefore estimated to contain 8 per cent. protein and 69.5 per cent. fat. If fat pork is taken there is a great deficiency of protein and an apparent excess of fats (320 gram.), but the fats are not excessive when it is considered that the active out door life of the camp with its exposures, makes necessary an increased supply of the fats. Indeed, 320 grammes are even below the amounts given by Atwater as consumed by various Massachusetts mechanics. As the bacon contains nearly as much fat as the pork and much more protein it would appear to be a better material for continued use, when fresh meat is not procurable, and it is probably preferred by a majority of officers. If ham or salt beef were used to supply protein, they would not contain enough fat nor relieve the desire for fresh meat. Both of these articles are taken into the field, and the salt beef, though derided during the war as "salt-horse," is even yet considered a desirable article by officers who used it for years Difficulty of transporting it on rapid marches weighs against it for field use; but for garrison use, an officer of large experience has lately spoken of it in very high terms, as an occasional issue optional with the company commander. In the future it may be entirely supplanted by canned meats, fresh or corned. If the camp is a permanent or large one, the matter of pork and bacon may not arise, for either a beef contractor will be on hand with cattle, or cattle will be purchased by the commissary officers, in accordance with regulations, and driven along with the troops when forage or grazing is procurable. There is an actual craving for fresh meat, and whenever it is possible, it is supplied by purchase; hunting is encouraged whenever practicable, but often fresh meat is entirely barred out by the barrenness of the country particularly in Indian campaigns. It is this need of fresh meat which induces the foraging expeditions of soldiers in camp—expeditions which often are disastrous to the occupied territory.

LIMITATION OF VARIETY OF DIET IN THE FIELD.

In the above field rations, the limitation of variety is due to either difficulty of supply or inefficiency of portable cooking utensils. The nearer the camp is to the markets of civilization, or the more permanent it is, the more nearly will the food approximate to what is used in garrison. There is no theoretical reason why the food in camp should be a particle different from what is used at home, provided there is more of it and there are more fats to supply the extra energy needed for warmth and work. The writer once asked an old packer and teamster accustomed for many years to the life of the wilderness, what kind of foods were best for camp; after considerable thought he answered, "anything good to eat," there was no theory in that answer—it was purely practical experience.

When soldiers are in the field and are limited to the bare ration, and more particularly when lack of transportation limits the ration to bacon, hard tack and coffee, they suffer very badly from constipation. Company commanders who understand this matter, have a simple remedy for their men, in dessicated fruits. These are purchased and carried along, and being light and uninjured by freezing they are always available. There is so much water in fresh fruit, that when dried out, 1 pound of evaporated or dessicated apples at 4 cents will make enough apple sauce for many men, and the expense to the company is trifling. The Canadian mounted police are said to have dried fruit as part of their ration. The commissary officer at Fort Assinniboine, Mont., Lt. J. F. Morrison, who used dried fruit in the field for his men, is very enthusiastic as to their great excellence in combating constipation. Besides all this, as antiscorbutics, they are of great value should the field service last any length of time, for though scurvy could never occur in garrison, there would be a tendency to it, with the above limited diet.

After hard work when one is depressed and worn out, there is nothing that relieves all ill feelings so soon as a hot drink that is at the same time stimulating. Spirits have been totally discarded with soldiers for this purpose as thoroughly vicious in results. Wines and beer are used in foreign services, but public sentiment will never allow them in the United States. It has been proposed to issue to soldiers in the field, extract of beef, whose stimulating qualities in the form of beef tea are too well known to be enlarged upon here. Now if the extract of beef can be combined with nourishment in the form of soups, a vast deal is to be gained. There can be no doubt that strong soups are highly appreciated in camp, and so experienced an officer as Capt. Spurgin states that it was his custom to make soup for his men, and that he found nothing like it as a hunger killer. Now, if the hunger-killer in the form of soup contains sufficient nutriment for part of a meal, it is a most desirable thing for hungry men who may have to sleep with the heavens for a tent. There is a popular delusion which ascribes to clear soups a much higher nutritive value than they possess. Raw bones contain considerable nutriment, not only fats but protein, and are capable of sustaining life. Though some animals can easily digest raw bones, man cannot; perhaps he could very readily if they were ground to powder. Pavy states that one pound of bones, contains as much carbon as there is in $\frac{1}{3}$ pound of meat, and as much nitrogen as there is in $\frac{1}{7}$ pound of meat. All this refers to raw bones, and in dilating upon the value of bones as a food, writers usually overlook a most important matter. The Paris Gelatine Commission, after ten years of uninterrupted experiments reported that "it is not possible by any known process to extract from bones an aliment which, either alone or mixed with other substances, can take the place of meat," and furthermore they reported that "every kind of preparation, such as decoction with water, the action of hydrochloric acid, and particularly the transformation into gelatine diminishes, and seems even, in certain cases, almost completely to destroy the nutritive quality of bones." After fifty years these conclusions, as far as known, are still accepted. By prolonged boiling of bones, the nitrogenous substances are converted into gelatine, which is dissolved in the water. Gelatine has been denounced as a totally useless agent, but it undoubtedly gives up some energy, though it is extremely doubtful if it is of any further use than as a fuel and a very poor fuel at that. It will not support life. When, therefore, the raw bones of beef are thrown away, the soldier loses very little available nutriment except the marrow, but there is a loss of variety of diet, and it has already been shown that variety though often impossible to obtain should always be sought. Soups add so much to attractiveness if nothing else, that they should be given at least four or five times a week in garrison, and in those companies where the bones are all carefully saved and boiled the men certainly do live better. Though all this is true of clear soups which may not contain much nutriment, it is entirely different with thick soups made from leguminous vegetables, or with other mixtures called soups. Pea and bean soup in particular contain quite a large percentage of the various alimentary principles. The difficulty of preparing the soups in the field is obviated by using one of the prepared articles mentioned more fully below. There is one in particular, consisting of a mixture of powdered peas, salts, extract of beef, herbs, etc., and sold in packages under the name of "pea-soup." The powder added to a quart of hot water makes in a few minutes a tolerably fair soup, rich, savory and nutritious. The published analysis, the accuracy of which is presumably correct, gives to a 3½ ounce package the following ingredients:

Protein, 21 grams; fats, 17¼ grams; carbohydrates, 46½ grams.

Now in the field ration there is a deficiency of nitrogen which can be remedied either by using more bacon or by the use of one of these prepared soups. One of these packages would therefore give a ration with the following values:

	Protein.	Fats.	Carbo-hydrates.	Calorics.
Maximum	127	337	586	5,614
Minimum	85	257	506	5,160
Average	106	297	546	5,387

A package of $2\frac{2}{9}$ ounces contains as much energy as the edible portion of the ration of potatoes (11 ounces) and a proposed package of 4 ounces has the energy of 1.8 rations of potatoes, though it contains far more protein and fat though less carbohydrates than the potatoes of the same amount of energy. It is proposed to use this prepared soup in the field in lieu of fresh vegetables allowed by law.

It may be added that in the field in war times, the transportation is usually insufficient. Officers of this military department know it and the subject receives constant attention throughout the world, for on it depends the success of the campaign. Notwithstanding all that is done, impediments will arise, break-downs occur, and roads become blocked. This always results in deficiency of food, for the rations in enormous quantities may be near by but unattainable, and the troops may be actually incapacitated for good fighting. This state of affairs may occur at any time and it is usually unavoidable. Again, in forced marches troops may be able to outstrip the wagon trains and then they must carry their own food. Numerous field dietaries containing ordinary articles of diet have been suggested from time to time for those special conditions, but as they have had time to crystalize into some definite shape and have not done so, it is presumed that they are mostly impracticable.

PREPARED FOODS.

For the same reasons already mentioned above, condensed and prepared foods have probably occupied the attention of military men from time immemorial; and Parke's Hygiene in speaking of these foods says: "For the military surgeon this subject is so important that it is desirable to put the chief facts under a separate Section." He then gives a list of many preparations of powdered meats, etc., but unfortunately states that many of these were unsatisfactory.

The difficulty in preparing and preserving foods is yearly becoming less and less. It is only within recent years that much attention has been paid to the proper preservation of fresh foods, and we can confidently expect in the future to see much further advance. Specially prepared foods have also attained a high degree of excellence; those intended for infants and invalids receive most attention because most demanded. Of the foods for adults probably the most successful so far are the prepared soups. The German army has had for a long time its Erbswurst, a mixture of pea-meal, fat, bacon, herbs, onions, etc., put up in little sausage-like rolls to be carried by the soldiers. Its present percentage composition is not at hand, but it is said to contain protein, fats, carbohydrates and salts in about the proportions needed in a food. The latest preparations are the pea and bean soups, made by an English, and several American firms. In each case the material is a powder more or less dry, and in some cases compressed, and when added to hot water makes a good soup, which is quite palatable to the majority of people. Lieut. W. C. Brown, 1st U. S. Cavalry, to whom the writer is indebted for all of the facts relative to the prepared soups, has used them in the field when the weather was very hot, and when a blizzard buried his camp under 12 inches of snow, and he speaks in no uncertain terms of their great value and excellence, and of the ease with which they can be preserved, transported and made ready for use.

There are very numerous prepared foods, either cooked, condensed, or compressed, which are being brought forward for use in such circumstances as surround people in camp. Dessicated vegetables have been given a trial in the U. S. Navy, and as far as known have not proved objectionable. Almost every variety of food is now being put up in the fresh state and preserved indefinitely, but most of them, particularly the fruits and vegetables are not suitable for military use in the field on account of their bulk, and their inability to stand rough handling, and the extremes of temperature. For garrison use at isolated posts where there is no market there is no reasonable objection to them. The great value of evaporated fruits for field use has already been mentioned, and they can be so compressed by machinery as to obviate objections as to bulk.

The universal experience of military men testifies to the absolute necessity of tea or coffee. The latter is generally preferred, but the writer's experience points to tea as preferable in the long run. Now each is difficult to carry and protect from damage, and the experience of foreign services is to the effect that if they are compressed into small bulk a vast improvement is made as to facility of transportation and preservation. In our own service during the civil war, extract of coffee combined with milk and sugar was issued in lieu of coffee and sugar, but with what degree of satisfaction the writer is ignorant. At the present time these compressed teas and coffees are quite satisfactory in other services.

A discussion of condensed food among military men brings forcibly to light a false conception which all non-medical men are apt to foster. It is believed that foods can be so extracted and condensed that a teaspoonful will be of the same value as a pound of the crude food. Beef extract is often held up as the ideal concentrated food. It is forgotten that what a man wants is so many ounces of combustible material for its heat energy, and that beyond the concentration due to exclusion of water and indigestible portions nothing further is practicable. Indeed, it is not improbable that a few officers believe that it ought to be practicable to so condense foods that a soldier can carry in his watch fob enough for a week. When a ton of anthracite coal can be compressed into a water bucket, then and then only can foods be condensed to suit such beliefs.

It is well known that on rare occasions the soldier is called upon to perform the most laborious duties, under almost inconceivable exposures and hardships, and it can well be assumed that at such times his food should be liberal, to the point of extravagance. But unfortunately it is in just such circumstances that it is impossible to carry along the necessary appliances. It is purely then a matter of transportation, and the most concentrated foods are the only ones carried—bacon, hardtack and coffee—a scorbutic diet. Omitting thoughts of plum pudding and pound cake, he must even be deprived of things that in civilization are considered necessary—a baked potato would be a luxury. These are the circumstances in which the Erbswurst of the Germans and the dried pea soup of the English have found their greatest efficiency. It is understood that in the wilds of Africa and Asia, the English troops found the latter food of the greatest utility, on account of the impossibility of transporting anything bulky. As lack of transportation bars out potatoes first, it has been suggested by Lieut. W. C. Brown to issue the above pea soup or similar preparation, in lieu of potatoes. This will be done as there is probably ample authority by law, and it can be done without increasing the ration. It is believed that the matter is being giving very earnest consideration in our own army.

OBJECTIONS TO PREPARED FOODS.

The one great objection to prepared foods is the ease with which adulterations and other frauds can be perpetrated. Quality of foods can be easily determined if seen in the natural state, but let them be ground up and mixed with other things, and fraud may be difficult or impossible to detect. Good housekeepers will not buy with their eyes shut. The above objection applies far more forcibly to military foods where the consumer is never the purchaser, the cupidity and avariciousness of contractors is greatly stimulated. It is a strange fact that though contractors know that at times the lives of the soldiers and the safety of the nation may depend on the character of the army supplies, they will yet jeopardize the lives of thousands of men by fraudulently supplying inferior articles. The disasters and sufferings during the Crimean war were increased to a great extent by the poor grade of supplies. The military history of the United States furnishes a host of illustrations of operations and even campaigns being hampered or even made disastrous by faulty food. The German government escaped this dilemma by making its own Erbswurst, and if any government makes its soldiers' arms, ammunition, clothing and shelter, it can surely make his food. The objection is lessened when it is remembered that prepared foods are not intended as a sole diet, but merely to piece out the notoriously rough field diet, and the objection may entirely disappear by an efficient system of analysis and inspection. Above all this it may be argued that if easily transported prepared, cooked foods are to be a valuable innovation, it might be justifiable to run the risk of being occasionally furnished with inferior grades, a risk that we run in the majority of mercantile transactions.

During the civil war, it is stated that roasted and ground coffee was greatly objected to on account of adulteration, but it has also been stated that the adulteration was done openly, ground and roasted rye being purchased for the purpose. In regard to adulterated coffee the writer has seen somewhere a statement that the average soldier prefers coffee that is adulterated with chiccory.

Another objection to concentrated foods as a sole and continuous diet is the fact that they do not furnish enough bulk of food. Though they may contain the proper amounts of energy and alimentary principles they can never be used exclusively. But they are not intended to be so used except in emergencies and for short periods.

TRAVEL RATION.

When cooking is impracticable on account of traveling by cars, or rapid marches or for other reasons, a special cooked ration is issued. The items of this ration are stated in table 9.

TABLE IX.—TRAVEL RATION.

Meat	12 oz. canned beef, fresh or corned.	Total weight, 2 to 2½ lbs.
Bread . . .	18 oz. soft bread or 16 oz. hard bread	
Vegetables .	¼ to ½ lb. baked beans.	
Coffee . . .	21 cents a day for the purchase of liquid coffee en route.	

The above has the following composition (approximately):

		Protein.	Fats.	Carbohydrates.	Calories.
Grams .	Maximum	150	170	417	3,900
	Minimum	120	91	380	2,900
Mean		135	132	400	3,400

This ration is insufficient for active men, being equivalent to the food of men of sedentary habits. The protein is the only ingredient in nearly the proper amount, and this arises from the meats and beans. As this ration is intended for short periods of inactivity (on cars, etc.) it might be said that the insufficiency is more apparent than real, but as men traveling usually develop enormous appetites they may need more than when in garrison. Nevertheless, it might be improved by the addition of prepared soups as in the case of the field ration.

A further defect of this ration is the inability of a man to carry enough for several days should military necessity compel him to be detached from the main command, carrying dispatches, scouting, etc. On such occasions he must learn to do as the Indian does,—twice a day take a drink of water and tighten his belt.

COMMUTATION OF RATION.

When small parties of soldiers are detached and it is impracticable to furnish them either cooked or uncooked rations and they are so situated that they can buy their meals, they are paid a certain sum in lieu of food. The ration cost about 14 or 15 cents (approximately) but when the soldier is on leave he is allowed 25 cents a day, when on detached duty 30 cents (non-commissioned officer 40 cents) and when traveling $1.50 a day.

TABLE X.—COMPARISON OF FOODS OF SOLDIER WITH VARIOUS OTHER DIETARIES.

	Grams.				Grains.	
	Protein.	Fats.	Carbohydrates.	Calories.	Nitrogen.	Carbon.
German soldier (peace footing)	114	39	480	2800	277	4443
Fully fed tailors, England	131	39	525	3055	318	4862
Travel ration, U. S	135	132	400	3400	328	5194
Machinist (Connecticut)	105	147	399	3435	255	5145
Factory operatives (Massachusetts)	111	150	522	4000	277	6048
Factory operatives (French Canadians) Mass .	118	204	549	4630	287	6901
German ration, war (extraordinary)	157	285	331	4650	382	6750
U. S. garrison ration (including canteen) . . .	152	180	570	4621	370	6805
Same (including beer)	155	180	633	4907	377	7446
U. S. field ration (average)	85	280	500	5000	206	7247
Machinist (Massachusetts)	182	254	617	5640	442	8423
Teamsters, hard work, Massachusetts	254	363	826	7805	617	9950

The U. S. rations would be slightly increased by including the amounts of nutriment in the articles of table 5.

Table 10 is prepared to show at a glance how the various rations discussed compare with the food of civilians. They are tabulated with various dietaries that have been published by Atwater. It is thus shown, that as far as the total energy is concerned the various rations compare rather favorably with the dietaries of various laborers in the United States. Only one dietary of foreign laborers is given for they are all less than those of American laborers of the same grade—the foreign workman, according to Atwater, being as much underfed as some American workmen are overfed. The field ration would be reduced in carbohydrates if potatoes could not be carried. Taking the largest dietary on the list as unity,—that is, the food of teamsters in Massachusetts doing hard work,—the energy of the various rations would be as follows: Field ration $\frac{10}{15}$; garrison ration, $\frac{9}{15}$; travel ration $\frac{7}{15}$.

The rations of foreign armies approximate to the usual food of the people, which as we have just seen is less than that of Americans; for this reason it is unfair to compare the U. S. ration with that of foreign armies, unfair to the former, which by the contrast appears more liberal than it is, unfair to the latter which similarly is apparently illiberal or actually deficient.

TABLE XI.—ESTIMATED PROPORTIONS OF ORDINARY DIETARIES.

	Protein.	Fat.	Carbo-hydrates.	Salts.
Playfair (moderate exercise and soldiers in peace)	100	33	443	17
Moleschott	100	65	315	23
Pettenkofer & Voit	100	87	258	22
U. S. travel ration	100	98	296	21
Ranke	100	100	240	25
U. S. garrison ration	*100*	*117*	*100*	*21*
U. S. field ration	100	329	588	21

The larger percentage of fats over protein in the U. S. rations in table 11 corresponds to the increased proportion of fats over protein found in all American dietaries according to Atwater, a still further evidence of the unfairness of comparing the U. S. ration with that of foreign soldiers.

SPECIMEN DIETARIES.

There are given in tables 12 and 13, a week's bill of fare taken at random and furnished by two company commanders, one at Fort Assinniboine, Montana, and the other at a hot southern post. These two are in the strongest contrast, the first so liberal, and the latter so bare, that they exemplify in the most fortunate way some of the remarks previously made as to the conditions of service varying the bill of fare. The company at Fort Assiniboine possessed an excellent cook and a large company fund, received nearly $50 a month from the Post Exchange, at the time chosen had vegetables from a fairly good garden, and could purchase extras fairly reasonably from neighboring towns and even St. Paul, but none of the conditions were as good as at other posts with excellent gardens, large receipts from the Exchange and convenient to good markets. The other company had no fund, no receipts from Post Exchange, no garden, no markets even if they had money to buy, and the result shows what the ration itself can do, supplemented as it was by $\frac{3}{4}$ to 1 pound potatoes daily per man purchased from meagre savings. Its commander also states as one reason for small "savings" that many of the soldiers are not much more than boys, and that they discover eating abilities surpassed by none except Indians. He is thoroughly alive to the interests of his men and gives much thought to the ration, and when favorably situated the company fared excellently. The bill of fare can therefore be correctly assumed to be the best that could have been done.

TABLE XII.

A company's dietary at Fort Assinniboine, Montana (Capt. Alfred Reynolds' Company).

December 1, 1891.

(Gravy always served with meats, and sauce with puddings.)

Breakfast: Beef stew, fried potatoes, corn bread, syrup, bread, butter, coffee.

Dinner: Meat pie, mash potatoes, turnips, cabbage, pickled pork, bread, coffee.

Supper: Beefsteak with onions, squash pie, bread and coffee.

December 2, 1891.

Breakfast: Roast beef, fried potatoes, bread, butter, coffee.

Dinner: Pea soup, roast beef, baked potatoes, stewed onions, cauliflower, tapioca pudding, bread and coffee.

Supper: Meat stew, fried carrots, apple pie, bread, coffee.

December 3, 1891.

Breakfast: Oatmeal, milk, meat hash, bread, coffee.

Dinner: Sauerkraut, pickled pork, mashed potatoes, pickbeets, rice pudding, bread and coffee.

Supper: Fried sausage meat, fried potatoes, green corn, blanc mange pudding, bread and coffee.

December 4, 1891.

Breakfast: Beefsteak with onions, fried potatoes, bread, coffee.

Dinner: Roast beef, mashed potatoes, stewed onions, pickled beets, plum pudding, bread, coffee.

Supper: Fried liver and bacon, fried carrots, squash pie, bread, coffee.

December 5, 1891.

Breakfast: Beefsteak, fried potatoes, bread, butter, coffee.

Dinner: Pork and beans, peach pie, bread, coffee.

Supper: Cold beef, corn bread, syrup, apple sauce, bread, coffee.

December 6, 1891.

Breakfast: Meat hash, oatmeal, milk, bread, butter, coffee.

Dinner: Vegetable soup, mashed potatoes, roast beef, pickles, tapioca pudding, bread, coffee.

Supper: Beef stew, green apple pie, bread, butter, coffee.

December 7, 1891.

Breakfast: Roast beef, baked potatoes, hot rolls, syrup, bread, butter, coffee.

Dinner: Sauerkraut, pickled pork, mashed potatoes, roast beef, bread, coffee.

Supper: Meat pie, rice pudding, bread, butter, coffee.

December 25, 1891, Christmas.

Breakfast: Meat hash, oatmeal, milk, hot rolls, bread, butter, coffee.

Dinner: Roast turkey, roast beef, green corn, French peas, ham, mashed potatoes, pickles, cranberry sauce, mince pie, jelly cake, sponge cake, bread, butter, coffee, almonds and filberts.

Supper: Oysters, cold ham, cold beef, apple sauce, assorted cakes, green apple pie, bread, butter, tea.

TABLE XIII.

A company dietary at a hot southern post.

(Gravy always served with meats, and sauce with puddings.)

April 1, 1892.

Breakfast: Beef hash, (with onions and potatoes) bread, coffee.

Dinner: Rice and tomato soup, roast beef, roasted potatoes, bread.

Supper: Beef, (same as dinner) bread, coffee.

April 2, 1892.

Breakfast: Irish stew, bread, coffee.

Dinner: Pea soup (with toasted bread), roast beef, boiled potatoes, bread.
Supper: Beef, pancakes, syrup, bread, coffee.

April 3, 1892.

Breakfast: Meat hash (with potatoes and onions) bread and coffee.
Dinner: Roast beef, mashed potatoes, plum pudding, bread and coffee.
Supper: Fried liver and bacon, bread and coffee.

April 4, 1892.

Breakfast: Beef hash, bread and coffee.
Dinner: Baked fresh pork, baked beans, bread and coffee.
Supper: Beefsteak, fried potatoes, bread and coffee.

April 5, 1892.

Breakfast: Irish stew, bread and coffee.
Dinner: Rice and tomato soup, roast beef, boiled potatoes, bread.
Supper: Beef, fried potatoes, bread and coffee.

April 6, 1892.

Breakfast: Beef hash, bread and coffee.
Dinner: Rice and tomato soup, roast beef, boiled potatoes, spiced bread dressing, bread.
Supper: Meat pot-pie, bread and coffee.

April 7, 1892.

Breakfast: Fried pork, fried potatoes, bread and coffee.
Dinner: Pea soup, with toasted bread, roast beef, boiled potatoes, bread.
Supper: Beef, fried potatoes, bread, coffee.

In view of the above bills of fare, and of all that has been said about the ration, it must be stated that it is a notorious fact that when sensational complaints from soldiers are published in the newspapers, it too often happens that when sifted down, they are shown to come from men who are inclined to be vicious, and who before enlistment have been accustomed to far worse fare, but who think that to complain is sure evidence of personal superiority. These cases are apt to dampen the ardor of officers, who with rare exceptions, are thoroughly interested in the soldier's welfare.

For the major part of the data of this paper the writer is indebted to the courtesy of the officers serving at Fort Assinniboine, Montana, who have with painstaking care weighed and determined the foods used in their respective companies and supplied all data at their command.

ERBSWURST.

Of the legion of prepared foods that have been used for military purposes the only ones that have given much satisfaction, and to which there are few objections, are those made with powdered peas as a basis. In some armies these are now always sent into the field with troops to be used when other foods cannot be supplied. As Erbswurst is the pioneer of this class, and has been frequently referred to, a few words as to what it is may not be out of place, though they may repeat former reports to this Section. Captain Henry G. Sharpe, C. S., U. S. Army, who has devoted much time and study to this subject both at home and abroad, has very kindly furnished the following information from his reports.

"Erbswurst is a combination of pea meal and other articles, invented by a German cook named Grünberg, whose secret consisted in his method of preserving the legumine from the decay to which it is so prone. The German Government purchased the secret for $25,000. It was first used on a large scale in the Franco-Prussian war by the II army commanded by Prince Frederic Charles, who reported its great value to the war ministry July 16, 1870. The food was composed of pea meal, fat and bacon, and an extensive factory for making it was established at, Berlin, under the supervision of Army Intendant Englehard. The factory commenced work on August 8 and in a few days furnished the first 100.000 pea sausages which under the name of "Erbswurst" became so widely known. This article of food met with such general approval that for a long time the factory had to supply the whole army with it. The factory ultimately extended its business to making other kinds of meat preserves and altogether sent some 40,000,000 rations to the field army. Other factories were established at Frankfort-on-the-Main, and Mainz.

This description of food had the advantage for the commissariat in being lighter for transport, and for the troops, especially for those on outpost duty, in being more easily prepared for consumption. The unavoidable sameness of the ration, was successfully compensated for by the large stores of wine found in the neighborhood of Paris, and by the occasional issue of an extra ration of brandy."

Parke's Hygiene states that when it was used too constantly not only did the men dislike it but it was liable to produce flatulence and diarrhœa. A soldier who has lately returned from a visit to Germany informs the writer that the soldiers in private conversation still speak of it in the highest terms. On account of certain seasoning ingredients in Erbswurst the English soldiers do not like it, though they are very fond of their similar preparation of pea soup.

TABLE XIV.—COMPOSITION OF SOME PREPARED MILITARY FOODS.

	Water.	Protein.	Fat.	Carbo-hydrates.	Wood-fiber.	Ash.	Authority.
Erbswurst	12.09	31.18	3.08	17.50	. .	6.15	Blythe.
" as first used	. .	16.00	35.00	27.00	. .	. .	Parkes.
" 1887	. .	15.70	23.00	. .	. .	. .	"
Dried pea soup (1)	7.58	16.93	8.98	53.44	1.34	11.73	Konig.
" " " (2)	8.08	15.81	21.11	36.78	1.69	13.53	"
Kopf's " " (used by the English army.)	4.78	21.09	17.25	46.45	4.40	6.03	S. P. Sharpless (Boston).

In table 14 are arranged some analyses of these pea-meal mixed foods. The English pea-soup appears to be drier than the others, and as the actual analysis above shows it to be so, it will probably keep better than the others. The percentage of fat though not great enough for American stomachs is far more than the first specimen of Erbswurst. If it were more fatty it would not keep as well as it does. Several American firms make dried pea soups and it is regretted that analyses of their products are not available for comparison.

Medical Education of Women in Russia.—The establishment in Russia of a separate school of medicine for women which many people had hoped would soon be an accomplished fact has been postponed probably for an indefinite period. It is stated that the project has been set aside through the influence of the Minister of religion, who views the higher education of women in anything but a favorable light, being persuaded that the study of medicine leads to materialism and nihilism.

THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

The recent Convention of representatives of the Southern Medical Colleges, held in Louisville, and the wide spread interest in this subject makes it pertinent at this time for THE JOURNAL to publish the proceedings of the meeting of The Association of American Medical Colleges, held in Detroit June 8, including the Constitution of that organization.

CONSTITUTION.

ARTICLE I.

This Association shall be known as the ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

ARTICLE II.

§ 1. Colleges adopting and observing the rules of this Association, as herein provided, shall be eligible to membership. Each college shall be entitled to one representative at all the meetings of the Association.

§ 2. Colleges desiring membership in this Association, shall make written application to the Secretary, officially signed, and pay to the Treasurer of this Association the sum of five dollars ($5), annually, in advance.

ARTICLE III.

§ 1. Members of this Association shall require of all matriculates an English composition, in the handwriting of the applicant, of not less than two hundred words, an examination by a Committee of the Faculty, or other lawfully constituted Board of Examiners, in higher arithemetic, algebra. elementary physics and Latin prose.

§ 2. Graduates or matriculates of reputable colleges or high schools of the first grade, or normal schools established by State authority, or those who may have successfully passed the entrance examination provided by the statutes of the State of New York, may be exempted from the requirements enumerated in Section 1.

§ 3. Students conditioned in one or more of the branches enumerated as requirements for matriculation, shall have time until the beginning of the second year to make up such deficiencies; provided, however, that students who fail in any of the required branches in this second examination shall not be admitted to a second course.

§ 4. Colleges granting final examination on elementary subjects to junior students, shall not issue certificates of such final examination, nor shall any member of this Association confer the degree of Doctor of Medicine upon any person who has not been first examined upon all the branches of the curriculum by the faculty of the college granting the degree.

§ 5. Candidates for the degree of Doctor of Medicine shall have attended three courses of graded instruction of not less than six months each, in three separate years.

§ 6. Students who have matriculated in any regular college prior to July 1, 1892, shall be exempted from these requirements.

ARTICLE IV.

§ 1. The officers of this Association shall be a President, Senior and Junior Vice-Presidents, Secretary and Treasurer, and a Judicial Council of seven members: all of whom shall be elected annually by ballot and serve until the election of their successors.

§ 2. The President, or one of the Vice-Presidents in his absence, shall preside at all the meetings and perform such duties as parliamentary usage in deliberative assemblies and the By-Laws of this Association may require. Of the seven members constituting the Judicial Council, the three whose names appear first on the list of those first elected shall serve three years. Of the remaining four, the two first named shall serve two years, and the two last named shall serve for one year. Vacancies by expiration of term to be filled at the annual election of officers. Vacancies by death or resignation may, if business of importance arise, be filled by the surviving members in the interval between the annual meetings of the Association.

§ 3. The Secretary and Treasurer shall record the proceedings of the meetings, conduct the correspondence, receive dues and assessments from members, disburse the funds of the Association as provided by resolution, issue certificates of membership, and perform such other duties as the By-Laws may require.

§ 4. The Judicial Council shall investigate and determine all questions of violation of the rules and regulations of this Association, and all matters of dispute between the members of this Association. All charges or complaints shall be preferred formally in writing, and referred to the Council. The Council shall make written report at the next ensuing session of the Association, upon all matters received for adjudication.

ARTICLE V.

§ 1. The stated meetings of this Association shall occur annually on the day next succeeding that designated for the annual assembling of the American Medical Association.

§ 2. A majority of the members shall constitute a quorum.

ARTICLE VI.

This Constitution shall not be altered or amended, except by written notice to all the members, at least thirty days previous to a stated meeting, and by a vote of two-thirds of all the delegates present at such meeting.

The following papers were read and discussed at the last annual session:

TO WHAT EXTENT SHOULD CLINICAL INSTRUCTION BE AFFORDED STUDENTS OF MEDICINE IN REGULAR COURSE.

BY N. S. DAVIS, M.D., LL.D.,

DEAN OF NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, (CHICAGO MEDICAL COLLEGE,) CHICAGO, ILL.

The subject of Clinical Instruction, as a part of the regular medical training required for the student during his attendance on his college courses, is one of much importance, and should receive more attention than has been hitherto given it. That the student should receive sufficient true clinical training to make him familiar with the means and methods of the examination of patients, the diagnostic symptoms of diseases, and the application of remedies, before being authorized to commence the practice of medicine and surgery, is generally admitted.

Whether such clinical training should take place while the student is actively engaged in prosecuting his medical college studies, or should be assigned to *one or two years after* he has completed the college curriculum, is a question concerning which much might be said. If the student is required to have a good general education and a fair degree of mental discipline before he commences the study of medicine, four years is certainly as long a period as three-fourths of the students can afford to spend in strictly professional study before they commence practice. Admitting this to be be true, I think both reason and experience show that the first of the four years should be devoted exclusively to the study of anatomy, physiology, chemistry, and materia medica with abundant practical work in the anatomical, histological, physiological and chemical laboratories with no clinics. But having thus gained at least an outline knowledge of the human body and its functions in health, and some knowledge of medicines, the student is fairly prepared to profit by one or two hours of direct clinical instruction each day during his second, third and fourth annual college courses. Such clinical instruction, however, should not be given to large classes in college and hospital amphitheatres or crowded wards, as is too generally done; but it should be so graded as to permit of adjustment to the need of each year's class, corresponding with the grading of the several branches of the curriculum, For example, the first year of clinical instruction. which would correspond with the second year of medical study, should aim to make the student personally familiar with the physiogonomy and symptomatology of diseases, and with the use of all instruments and appliances for accuracy of examination and diagnosis, both medical and surgical. The second clinical year should be chiefly occupied in the study of the actual pathological processes taking place in the different forms of disease and their relation to the symptoms, including personal examinations, chemical and microscopic, of the secretions and excretions in the several stages of progress of disease, as well as the tissue changes to be found after death. With these studies, the objects to be accomplished for counteracting the morbid processes, correcting the secretions, and preventing permanent or fatal tissue changes, should be clearly indicated. Having thus become clinically familiar with the symptoms, diagnosis and pathology of diseases and the indications desirable to fulfill in their management, the third clinical year should be devoted directly to the study of methods and means of treatment, preventive, hygienic, therapeutic and surgical.

The advantages to be gained by such grading of clinical studies as I have just indicated must be obvious to both the student and the clinical teacher: 1. By giving to each year of clinical study, limited and definite objects, the accomplishment of which makes his next year's work easier and more thorough, you not only make the student's practical knowledge more systematic and comprehensive, but you add much to his mental discipline and accuracy of observation. 2. Such a system necessarily limits the number of students in any one clinical class, and in the same ratio increases the opportunities and value of individual training, which is the most essential feature of all true clinical study. The dispensaries and hospitals of our larger cities in which the medical schools are chiefly located, contain an abundance of clinical material, that needs only judicious arrangement and faithful attention to secure both the most complete clinical instruction and the most skilful service for the sick. But as the subject is to be before you for further discussion, I will not occupy your time with details at present. The principle or system of grading the clinical instruction of students during their consecutive courses of medical college attendance, will be found no less important and advantageous than is the proper grading of the various branches of medicine contained in the college curriculum.

THE KIND AND AMOUNT OF LABORATORY WORK WHICH SHOULD BE REQUIRED IN OUR MEDICAL SCHOOLS.

BY VICTOR C. VAUGHAN, A.M., M.D.,
DEAN MEDICAL DEPARTMENT UNIVERSITY OF MICHIGAN.

Mr. President and Gentlemen:—It will not be necessary for me to take any time in giving the arguments in favor of teaching medical students by the laboratory method many of the sciences which must enter into the curriculum of study. I will take it for granted that all reputable teachers of medicine understand that analytical chemistry, practical anatomy, bacteriology, histology, physiology, analysis of urine, pathology, etc., must be taught in the laboratory in part at least, if taught at all. How can you expect a practitioner to tell whether a given bit of tissue is from a malignant growth or not, when he has never seen a cancer cell? How could he be trusted with such an examination when he has never used a microscope, cut a section, or made a microscopical mount? How can the young practitioner diagnositicate tuberculosis in its early stages, when he has had no practical experience in staining germs and when he would not recognize the bacillus tuberculosis should it be placed before him? How can he detect tyrosine or leucine in the urine, when he does not know a crystal from an air-bubble? How can he recognize structural disease of the kidney when he does not know a cast from an epithelial cell? These questions suggest their own answers. It might be said, possibly, that many of the older men now practicing medicine and doing so satisfactorily, and, indeed, with credit to themselves and the profession, never had laboratory instruction in these branches. This is true, but these men have been compelled to take up these new studies and methods for themselves. Besides, more is expected in these directions from the recent graduate than from the older man. Medical schools should always give the best and the most recent information, and every fact which may possibly aid in the diagnosis or treatment of disease should be made known to the student. The student has the right to expect and to demand this of teachers, and all intelligent and conscientious students will do so. The time once was when the teacher was a model from which his students copied. The student measured his own success by the extent to which he imitated his master. Now, that teacher who does not give his student opportunities for independent and original work in science is to a large extent a failure. Just as in the general progress of the race, one generation should be wiser than the preceding, so every class should contain one or more students who will at maturity be wiser than the best teacher.

I will presume that all of us here agree that laboratory instruction should be given in medical schools, and with this presumption I will now turn to the question of what, in kind and amount, should this laboratory teaching consist.

We will suppose that the student has had a full course in a good high school or an equivalent of this. (The best medical colleges are not satisfied with a less requirement for admission.) The student is able to use the English language correctly, and he has a good drill in mathematics, including arithmetic, algebra and plain geometry. He has had, we will suppose, fair instruction in systematic botany zoology. He is acquainted with the general classification of plants and animals, and knows the meaning of the general terms employed in the natural sciences. He has some knowledge of physics, knows what is meant by the conservation of energy, and understands the fundamental principles underlying our knowledge of heat, light and electricity. I am aware of the fact that many medical schools admit students who have not these qualifications, but such a school does not comply with the rules of this Association, and I am to discuss the question of laboratory teaching in those colleges which belong to this Association and which live up to the requirements to which we have mutually and voluntarily pledged ourselves.

In the first place it will be convenient to specify what I mean when I speak of the number of hours, days or weeks given to a subject. We will suppose that there are five teaching days in the week, that the forenoon of these days are devoted to class instruction given in the form of lectures and recitations, and that four hours of each afternoon are spent in laboratory work. In certain schools this order may be reversed or some of the laboratory instructions, practical anatomy. for instance, may be given in the evening. With the understanding then that four hours shall constitute a day of laboratory work, I will outline such a course as I conceive to be essential to the student.

The courses of laboratory work which should be embraced in the curriculum are, 1. Analytical chemistry; 2. Practical anatomy; 3. Bacteriology; 4. Physiological chemistry, including the analysis of urine; 5. Histology; 6. Physiology, and 7. Pathology.

1. *Analytical Chemistry.*—The medical student should become acquainted with the physical properties, solubilities and general reactions of the salts of silver, lead, mercury, copper, arsenic, antimony, bismuth, iron, zinc, cobalt, nickle, barium, calcium, potassium, sodium, lithium and ammonium, which are employed in medicine. This knowledge cannot be properly acquired from a study of books alone.

The student must see these compounds, must dissolve them, and must ascertain their incompatibles by precipitating the bases and acids with various reagents. To do this properly, experience has shown that a course of twelve weeks is required. If a shorter time is given to this branch the work must be done superficially and the knowledge is but imperfectly acquired.

2. *Practical Anatomy.*—Each student should first have a thorough drill in osteology. With the bones before him he must study their size and shape, the nature of their articulations, the points of origin and insertion of ligaments, tendons and muscles and the location of foramina. Then he should carefully, slowly, intelligently, under the eye of a demonstrator, dissect every part of the body, and in doing so he must not only study position, size and physiological office of each muscle, but of the viscera, the blood vessels and nerves. My observation has led me to believe that too often dissection means nothing more than a study of myology.

If the student is to become a surgeon it is quite as important that he should know what blood vessels and nerves are to be severed in a given operation as to know what muscles he must traverse with his knife. If he becomes a general practitioner he will need to recall the anatomy of the viscera more frequently than that of the muscles. Every medical school should also offer a course in surgical anatomy. Of course the professor of anatomy dissects before the class and gives especial attention to the hernial region and other parts of the body upon which surgical operations are often necessary; but this is not enough. Such knowledge as this is what our legal friends would designate as hearsay. The positive knowledge can be gained only by the student using the knife himself. Knowledge thus gained becomes a part of himself and arms him with a consciousness of his own resources when he is called upon to do the operation for the first time upon the living body.

The osteology should be taught during the first part of the first year. Then the courses in dissection may follow, while that in surgical anatomy is of most benefit when given later in the course and at times when the student is in attendance upon the surgical clinics.

I think that twenty week's time is none too long for the osteology and the dissections, while four weeks more might be given to the operative work.

Bacteriology.—Practical bacteriology is taught as an under-graduate course in only a very few medical schools, but this is not as it should be. The germ theory is now, and has been for some years, much more than a theory, and the causal relation of certain bacteria to certain infectious diseases has been demonstrated with all the certainty of direct scientific experimentation. We all teach that tuberculosis, diphtheria, typhoid fever, etc., are caused by bacteria; that the detection of these bacteria in many cases offers the only early means of positive diagnosis, and yet only a very few colleges afford any demonstrative instruction in this branch. Every sanitarian speaks of the spread of typhoid fever by contaminated drinking-water, and still of the hundreds of medical students graduated in this country within the past three months only a very small number have any conception of the method or procedure necessary to detect the typhoid germ. The surgeon dwells upón the fact that the pyogenic germs give rise to suppuration, and seldom demonstrates these organisms to his students. Great stress is placed upon the necessity of examining the sputum in suspected tuberculosis, and yet hundreds of graduates of the present year would not know how to stain the germ nor would they recognize it were it stained and placed before them. We teach that in many cases the recognition of Loffler bacillus is the only sure means of the postive recognition of diphtheria, and yet how many teachers make their students acquainted with the practical means of recognizing this organism. There is just cause of complaint on this point. Schools which neglect this branch of instruction are not giving their graduates the proper equipment.

A course of bacteriology embraces the methods of the preparation of the various culture media, of the processes of obtaining pure cultures, of the nature of growths on the various media, of the effect of pathogenic germs on animals, and of the detection and identification of the germs in tissue, in sputa, in drinking-water, and elsewhere. Such a course should begin with the study of the non-pathogenic and proceed to that of the pathogenic bacteria. I have tried the teaching of bacteriology in all the classes of a four year's course, and find that I can teach this subject to the students of the first year as satisfactorily as to those of the fourth year. Indeed, there is an advantage in having this instruction given early in the course. The student who has studied the diphtheria bacillus, or that of a tuberculosis, in the laboratory, and knows the manner of their growth, and has watched their effects upon animals, will listen to his clinical lectures upon these diseases with greater interest and more intelligence than the student whose only knowledge of these organisms is confined to that of their names with some imperfectly understood text-book or lecture description of them. Ten or twelve weeks should be given to the course.

4. *Physiological Chemiscry.*—This course should

embrace a chemical study of the most important secretions of the body. The test for hydrochloric and lactic acids in vomited matters, the recognition of the digestive ferments and the method of the determination of the activity of the same, and an analysis of the urine and bile, should be included. The student should be made perfectly familiar with the constituents of normal urine. In most medical schools the analysis of urine is limited to the detection of sugar, albumen and bile. Students with such training often mistake epithelial scales for casts, and pronounce every reducing substance found in the urine, sugar. I meet with mistakes of this kind frequently, and have known more than one physician to lose the confidence and respect of the patient and his friends by mistaking an epithelial scale for a cast. A physician is often pardoned for overlooking a serious trouble when it exists, but it is a sad mistake to tell some man that he has an incurable form of Bright's disease or diabetes, when nothing of the kind exists. The patient gets over his fright after a while, but he is not likely to forgive the doctor who has made the blunder.

I believe that analysis of urine should form a part of clinical instruction, but this work should be preceded by a scientific study of normal urine and the scientific methods of estimating the most important normal and abnormal constituents of the urine. The course in physiological chemistry will occupy not less than ten or twelve weeks.

5. *Histology.*—The medical man certainly must be able to recognize the various tissues of the body by their microscopical appearance. He must be acquainted with the methods of hardening specimens, making sections, mounting and staining the same. This knowledge can not be acquired from books or in the lecture room. Laboratory instruction in this branch is a necessity. This knowledge can be gained in a course of six weeks.

6. *Physiology.*—All medical teachers admit the necessity of practical dissection in acquiring anatomical knowledge, while but few schools give practical courses in physiology. Notwithstanding this, it is certainly true that the medical man needs to employ his physiological knowledge quite as often as he does his anatomical learning. When such instruction is properly given we will have much more intelligence displayed in the practice of medicine. One needs to know the anatomy of the heart in order to detect valvular diseases of that organ, but the number of functional diseases of the heart which one is called upon to treat is certainly greater than that of structural diseases of the same organ, and yet the student in most of our schools has no practical instruction in the innervation of the circulating system. How many of us were able from knowledge gained in our undergraduate course to intelligently apply electricity to any part of the body, to mark out anæsthetic areas which would result from injury to or disease of any nerve, to intelligently interpret the reaction obtained in testing the knee reflex, to properly ascertain the degree of sensation in any muscle, to explain the relation between injury to the floor of the fourth ventricle and the glycogenic function of the liver: or in short, did we have any positive physiological knowledge other than a general idea of the processes of digestion, absorption and elimination? Do we not feel the want of this training in the work of every day? Should we not see to it that our students have this instruction? A six weeks' course in laboratory [illegible] will in my opinion be of great service.

[illegible]—The necessity of practical instruction in this branch will be admitted by all. Such a course should embrace both gross and minute pathology. The bungling way in which post-mortem examinations are often performed, and the little information which the medical man usually gets from such an examination, afford abundant evidence of the fact that gross pathology is too much neglected in our schools. Without microscopical pathology the determination of the nature of many growths is quite impossible. Let us give six weeks to the deadroom and laboratory courses in pathology.

To sum up I would say that the following laboratory courses are essential:

1. Analytical chemistry, 12 weeks.
2. Pracitical and surgical anatomy, 24 weeks.
3. Bacteriology, 10 to 12 weeks.
4. Physiological chemisty, 10 to 12 weeks.
5. Histology, 6 weeks.
6. Physiology, 6 weeks.
7. Pathology, 6 weeks.

This makes a minimum of 74 weeks. The greater part of this work should precede clinical instruction. Besides the above mentioned courses, therapeutics, including electro-theraputics, is now being taught in some schools largely by laboratory methods, and this tendency will grow.

Laboratory methods will soon largely modify clinical teaching. Amphitheatre clinics are giving way to bed-side and section instruction. Laparotomies and other capital operations are now made by the students in some of our schools on dogs. The surgeon as well as the chemist has his laboratory. The student delivers the alcohol baby from the rubber mother before he is permitted to enter the lying-in room. It is no longer necessary to spoil a hatful of human eyes before one becomes a skillful ophthalmologist.

DISCUSSION OF DR. VAUGHAN'S PAPER.

BY BAYARD HOLMES, B.S., M.D.,
SECRETARY COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO, ILL.

Mr. President and Gentlemen of the Association of Medical Colleges:—The paper of Dr. Vaughan, which has interested us so much, suggests great changes in medical education. During the past year my attention has been called to some of the details of laboratory work which must be faced by every one of you. Allow me to very briefly speak of some of the results of my thoughts and studies.

Laboratory rooms must be light and roomy. Forty square feet of floor is the least amount which will accommodate a single student, and then only in the chemical laboratory. In all other laboratories at least sixty square feet of floor space, not including aisles, must be allowed each student. In the chemical laboratory students' desks may be placed twenty feet from the windows; in laboratories in which microscopes are to be used, fourteen feet is a maximum.

The ordinary medical class in the larger institutions ranges from one hundred down to thirty, and therefore the laboratory room should be, if lighted on both sides, not less than fifty by forty feet, and it may be lengthened but not widened. At the institution which I represent, our laboratory rooms were last winter twenty-five feet by sixty feet, lighted on one side and both ends; our largest class numbered ninety-four, and it was necessary, therefore, except in chemistry and bacteriology, to divide the class into two sections and then crowd them. Our new laboratories are attached directly to the old ones and are the same width (twenty-five feet), making each laboratory a room 160 feet long, lighted on one side and capable of accommodating eight students to each ten feet of length. This gives us, besides the necessary reduction for aisles and preparation rooms, accommodations for 120 students in each laboratory. This seems like a large class for laboratory work. So it is. And yet the fact that our laboratory teachers are practicing physicians makes it necessary to economize their time. They are unable to give the work the whole day, or every day in the week, and we believe, supposing an unlimited supply, that brick, stone, glass and iron are cheaper than men. This large laboratory class necessitates great and even elaborate system and unusually efficient teachers. Every man who can conduct a laboratory exercise creditably with a class of ten, will not be able to hold and instruct a class of seventy-five.

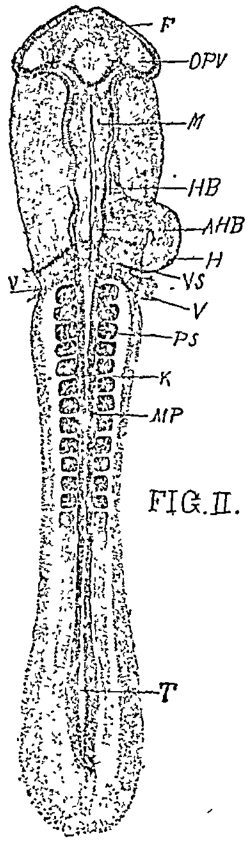

FIG. II.

The Normal Embryo.

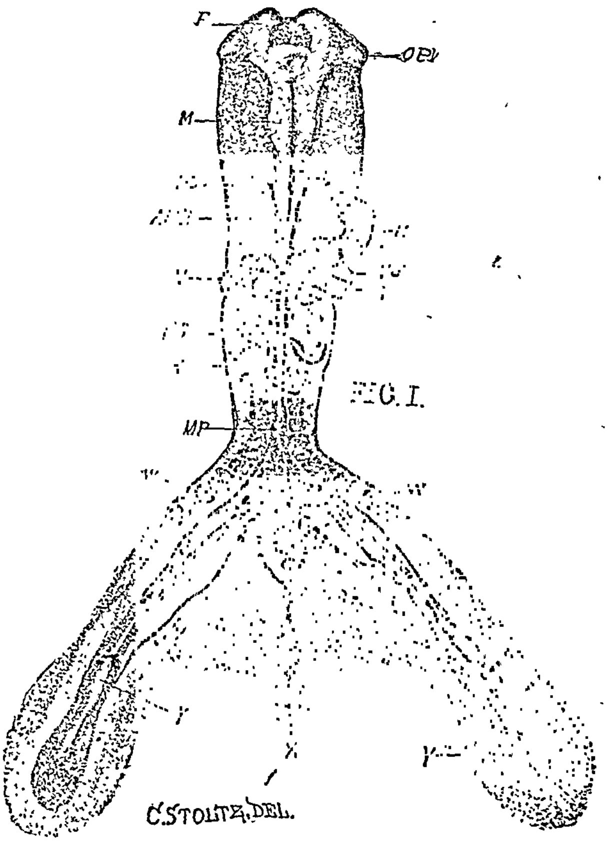

FIG. I.

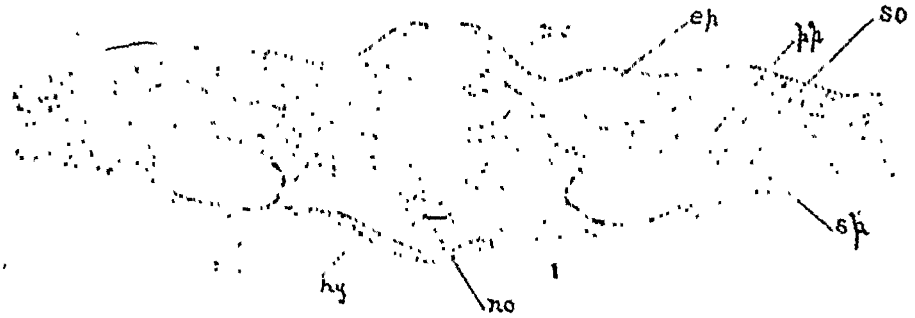
The Fissioned Embryo.

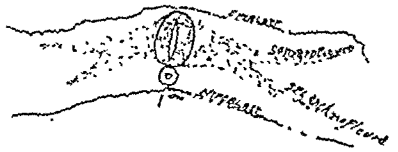
The order necessary requires such an arrangement of desks as will allow two sets of men to use each laboratory room. Our desks in the microscopical room have a flat surface $1\frac{1}{2}$ by $3\frac{1}{2}$ feet, of oiled white wood. There is a knee space two feet nearly, and two cupboards on the right, each locking with a Yale lock, and each eighteen inches square and two feet deep, in which are suitable drawers and shelves. The desks are built in pairs and the sides are stained white wood. Stools are provided that are about two inches higher than the ordinary chair and can be placed in the knee space when not in use.

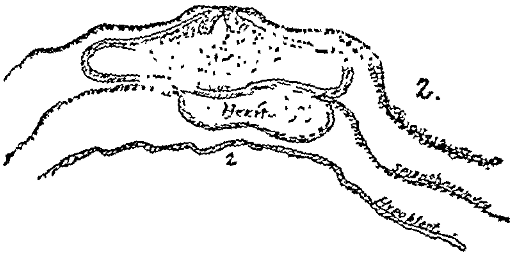
These details may be tiresome, but success in the laboratory work depends on the care with which these details are considered. One of the most important matters is the system of bookkeeping employed by the curator in keeping track of the supplies. We lost at least two thousand dollars unnecessarily from the neglect of this business-like forethought. Last term we started out with a single man for curator. The demonstrators furnished lists of material required for each of the nine laboratory courses which were conducted last term. A sufficient number of outfits were made up by the curator a month before the term opened. On an appointed hour the students selected their desks in the laboratory in the order in which they purchased their tickets. They went one by one to the store-room as their places were assigned and received each his outfit. In the outfit were two printed lists of the material contained. Each student compared his invoice with the outfit, signed the receipt on one invoice, left it with the curator, and after locking the desk put his key in his pocket and went out in an orderly manner. These receipted invoices were entered in a book which had two columns opposite each student's name, one for debits, one for credits, and a place for the student to sign his name on receiving his balance and closing the account. Students are encouraged to keep their outfits, as they are useful in promoting after study. They are paid for at cost, or a little above cost, out of a deposit fund placed with the treasurer for that purpose. By such a system the laboratories may be made a source of income, and not an expense to the college.

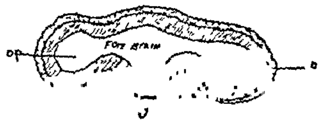
The equipment and supplies are purchased for the most part in Europe, on account of the enormous reduction which the law allows educational institutions in the rebate in imposts. It is necessary to put in all orders for European goods at least as early as March 1. In our laboratories we are using the Leitz and the Bausch and Lomb microscopes. We have now a sufficient number to give each man an instrument. We urge students to provide themselves with microscopes, and many of them do, especially the second year.



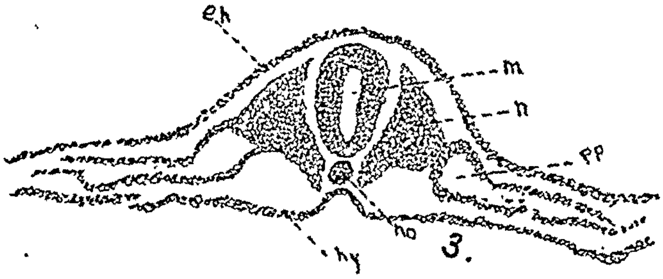
If I may be allowed the time, I should like to show you some drawings made last winter by second year men in the College of Physicians and Surgeons, in the laboratory of Dr. A. P. Ohlmacher, Professor of Embryology and Biology. These 250 or more drawings represent the work of *every one* of the class of seventy-two students, and they were a part of the final examinations on that branch. Under the directions of Prof. Ohlmacher and his two assistants, Mr. Stolts and Mr. Osincup, selected out of the class, each student opened his incubated egg, sketched and removed his embryo, fixed, stained, imbedded, cut and mounted it. He made drawings representing the different portions, and was quizzed on the drawings and the specimens under the microscope.



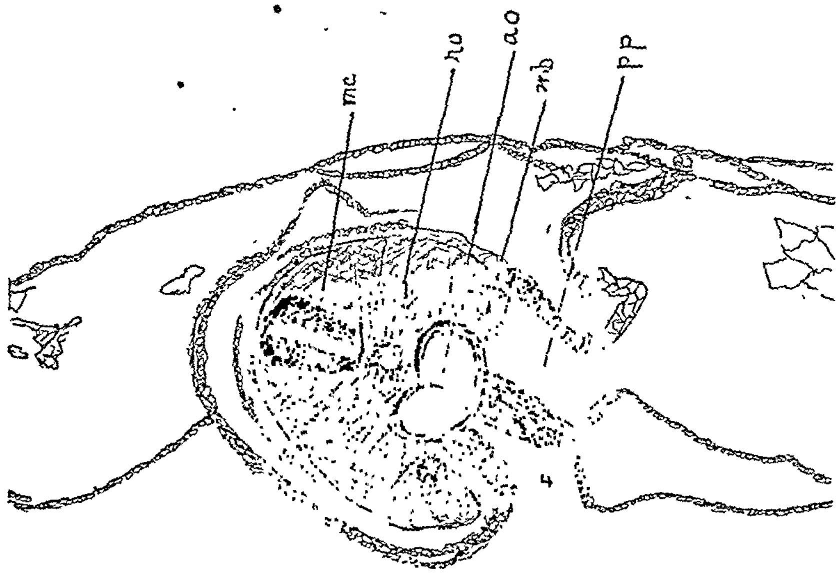




You will notice that in spite of the fact that there is a general *impression among students* that some cannot draw, there is not one disgraceful drawing in the lot, and there are at least two or three drawings from each student in a class of seventy-two. The class only studied the first four days of the embryo's development, so you will recognize all the parts.

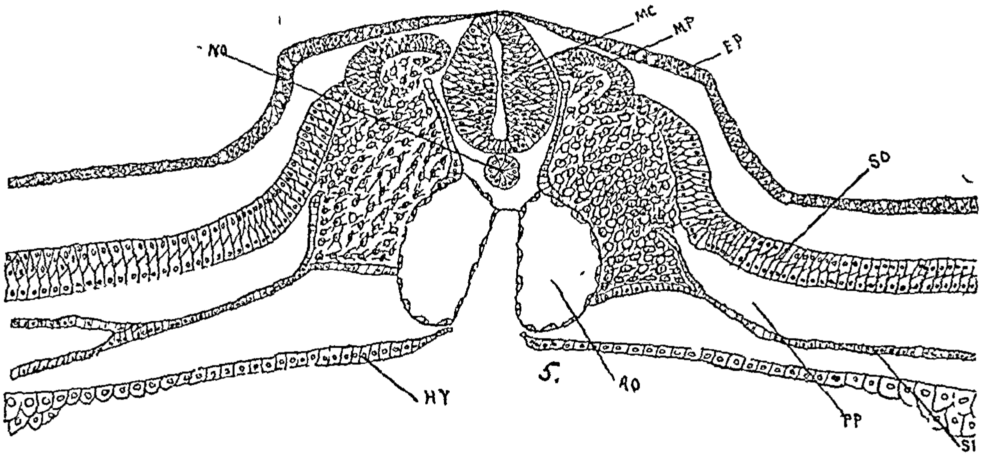


Let me call your attention especially to the drawing of the whole embryo by Mr. Stoltz. Each student made a sketch like this, but Mr. Stoltz, in examining a large number of eggs, found one with an error of development which he has described in full in the *Scalpel*, the magazine published by the students of the college. Both drawings are reproduced here to show the best free-hand drawing, without the use of a camera lucida or other projection device.

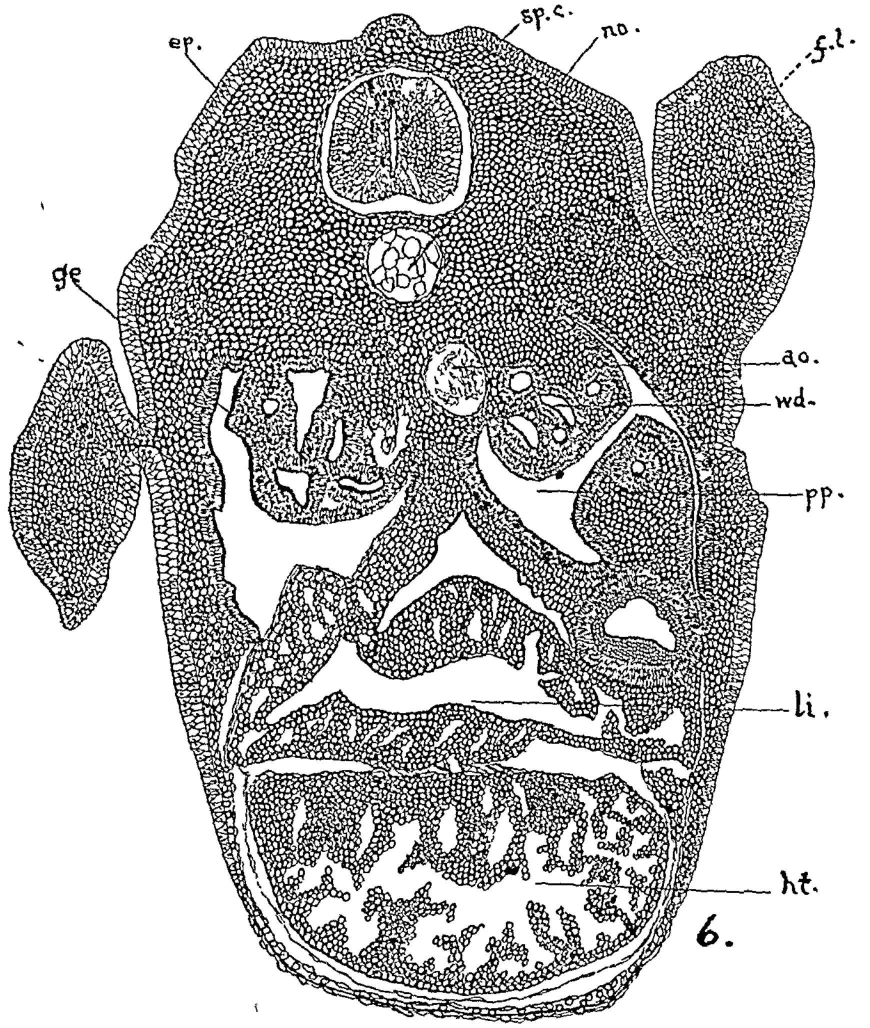


Perhaps the only original departure made by the

College of Physicians and Surgeons during the past year has been in the introduction of an extended course in Biology. This course really covers a course in comparative anatomy, a course in elementary physiology, and a course in the histological study of the elements of mammalian structure. As a whole, the course occupies ten hours a week, and has been most successfully conducted by Prof. Ohlmacher. If it will not tire you too much, allow me to show you some 300 drawings made during the present spring term by a class of twenty-two men who have just begun the study. The complete work of each man, as far as has been required, is before you. You will notice a greater difference in the mechanical execution here than in the embryology. The drawings in all the laboratories are made on paper furnished at cost by the College. It is of uniform size, 11 by 8½ inches, or 8½ by 5½ inches. The drawings occupy a definite portion of the sheet, leaving a margin of one inch all around, and a quarter of an inch more on the left hand end for binding. It is impossible to show this work on the printed page, but a few drawings will be reproduced by the photographic process, much reduced, in order to give a faint idea of the work.



5.

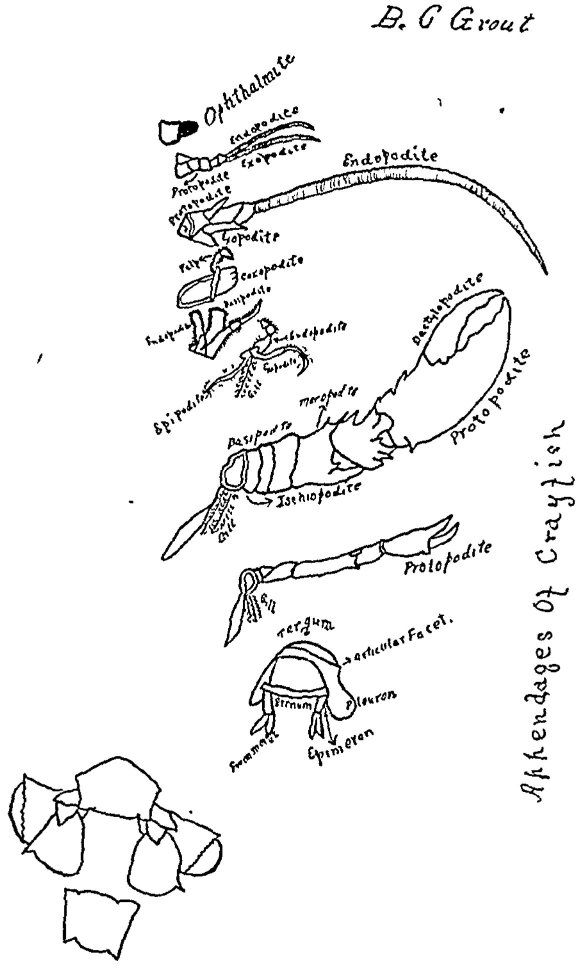


6.

Some of the best drawings are in colors and cannot be reproduced at all, others are too fine to stand reduction, and others have some shading which would require too expensive a method of reproduction.

Dr. Vaughan has given me one idea which is new, and that is of the position of bacteriology in the course. This branch has been placed in our schools in the third year, on account of its intimate connection with medicine and surgery, which fills the fourth year. There seems no reason why it should not appear earlier in the course. Systematic bacteriology could certainly be placed in the second year. Still, I believe that its value to the student would be increased by associating it with pathological study as we have done.

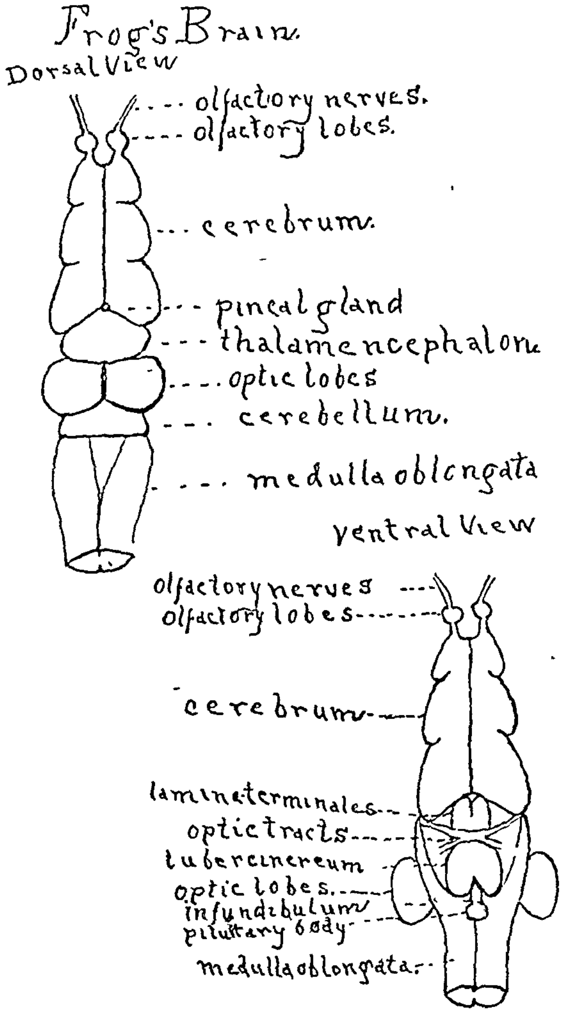
In regard to the length of laboratory hours, several points must be considered. Microscopical laboratories cannot conflict, because we do not have enough microscopes to equip two laboratories at once. Our men cannot spare more than three hours at a time out of their practice, and therefore it has been found necessary with us to make the length of each laboratory exercise two hours. There is no doubt that, had we the entire time of our laboratory teachers at our disposal, it would be better to make the unit of the laboratory exercise three or four hours, as the essayist has suggested.



On account of the necessity of one laboratory exercise following another without intermission, and on account of the necessity of some preparation in each laboratory room before each exercise, we have concluded that it is necessary to provide *at least* two microscopical laboratories. This we have done, and you will see by the time card how our exercises follow one another, and what portion of the student's time in each year's work is occupied in lectures and recitations, in laboratory work and in clinics.

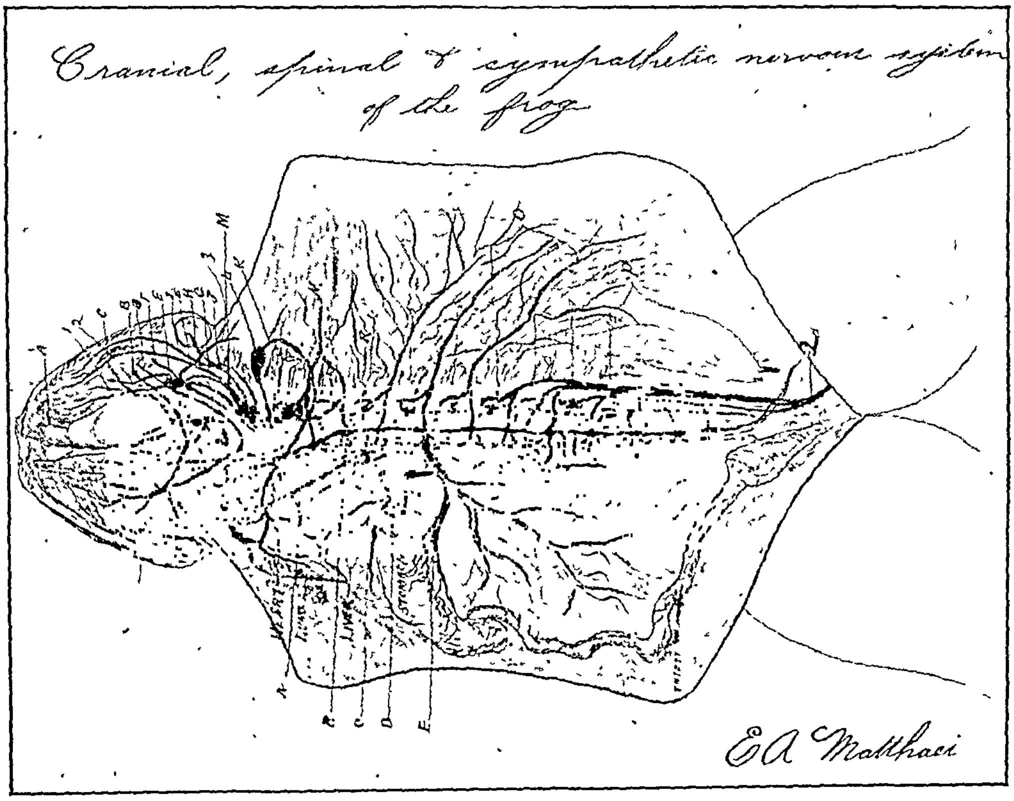
The introduction of laboratory work gives a new impetus to medical education in small cities. The work in this department can be done better, other things being equal, in small medical schools. I predict that these medical schools in small cities that adopt vigorous methods of laboratory teaching will rise to a prominence they could never have attained while medicine was taught by lectures and clinics alone.

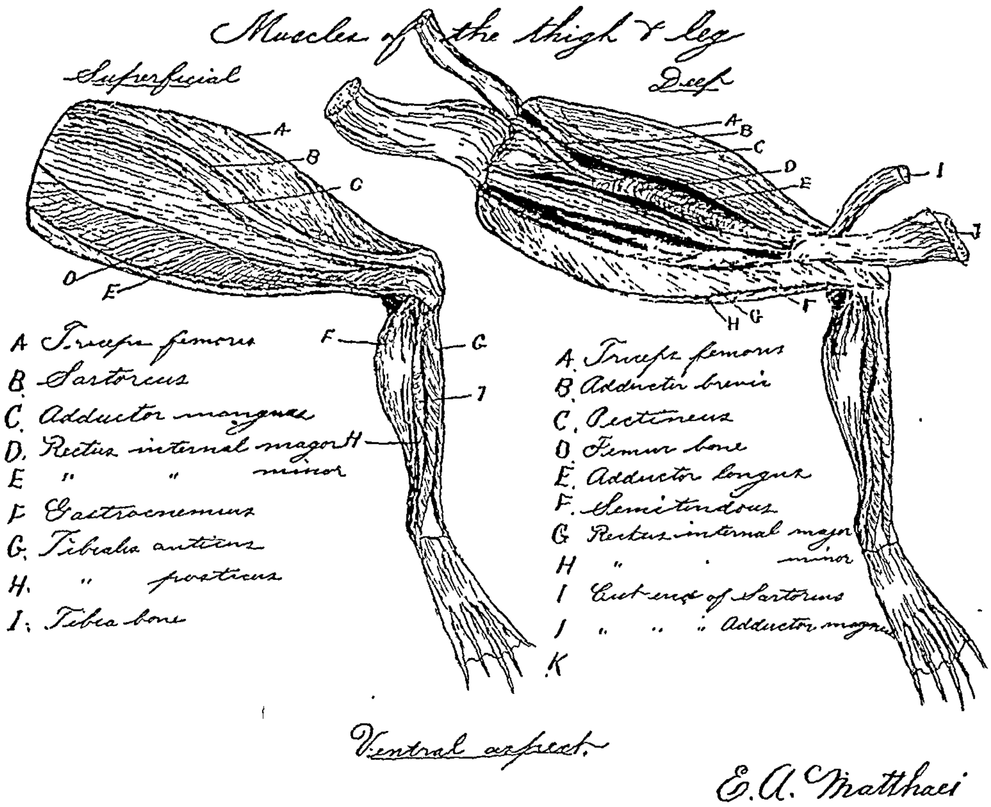
The laboratory teaching will also make a change in the character of medical students. The farmer or butcher medical student cannot hold his knees fifteen or twenty hours a week under the laboratory table throughout a four-year course. He will give place to the educated young men of 20, graduated now in such astounding numbers from the multiplying colleges all over the country, but especially the Central States. It should be our aim to secure these men, if we would have our efforts in medical education succeed.



J. C. Reming.

Again, in order to have our laboratory work done in a constantly efficient manner, it must be done by the same men for a long time. This requires money, and more money than any but the largest schools can obtain from students. *That is to say*, laboratory work calls for endowment. Only a few State Universities pretend to support medical schools, and so far as I know only one of these, Minnesota, contributes liberally to the annual expenses of the medical department. It seems strange that the department of the university, which should in this country furnish one-fourth of the entire enrollment, should not have received even 2 per cent. of the endowment. It should be the concerted effort of this Association to educate the generous public to a thorough understanding of our deserts and our needs.





The accompanying figures, numbered 1, 2, 3, 4, 5 and 6, represent reproductions of embryological drawings by several of the students in the class. They are all drawings of cross sections of embryo chicks of various stages of development. These drawings were made on the paper described in India ink, being copies of the class-room drawings which were first made in a note book with lead pencil. No text-book was used in the work of embryology, the work being guided by a few printed syllabi and by oral instruction. Hence the student had no illustration of the object he studied, save the picture his mind conceived. We may, therefore, take these drawings as representing the student's individual conception. The lettering of the various parts is made uniform only for the sake of easy comparison.

F. L. Mueller, May 1892.

Fig. 1 was drawn by Mr. J. F. Adams from a section of the tail end of a 36-hours chick. It shows very clearly the primitive germinal layers, splitting of the mesoblast, mesoblastic somites, notochord and medullary canal not completely closed. Fig. 2 represents three drawings by Mr. O. B. Monosmith, showing a section through the tail end, one through the heart region and one through the fore brain of a 36-hours chick, all from the same embryo. Fig. 3, from an embryo of about 50 hours incubation, by A. M. Fulton. Fig. 4 shows the amniotic folds and amniotic cavity very clearly, and was drawn by Mr. G. A. Hibbert. Fig. 5 is from a section through the hind end of a 3-days chick, by Mr. R. H. Herrold. Fig. 6 was drawn from a section of a 5-days chick, by Mr. J. J. Pierron, and shows the budding of the fore limbs, the development of the heart, liver, urogenital system, etc.

To anyone who has had experience in this kind of work it must be evident that many hours of painstaking labor have been spent in producing some of these drawings.

The few drawings of the spring class in biology here reproduced speak for themselves. They are copies of note book drawings made by the student as he dissected the animal chosen. Huxley and Martin's Practical Biology was used as a guide in the work on the crayfish and frog, and one familiar with this most valuable laboratory guide will know that it contains no figures of the dissections prescribed. Therefore, in this work, as in the course in embryology, the drawings are the student's representation of what he saw as he made his dissections. Moreover, this work of reproducing the curves, elevations and depressions, distinctions between organs, etc., of the *whole object*, is much more difficult than the reproduction of microscopical sections, as every scientific draughtsman knows.

In the biological class each student caried out his own work. He made all the dissections, injections and other preparations required, himself, and then made a drawing of the completed work which he copied on the sheets of paper furnished, either in India ink or in color. It will be noted that some of the work is plain outline drawing, while more ambitious students have shaded and colored their drawings most artistically.

Is it not reasonable to presume that a man who has dissected and verified all the intricate and minute relations of the cerebro-spinal and sympathetic nervous systems of the frog will go to his human subject with a determination of carrying out equally exacting studies? We believe that a student who has by his own labor produced such a drawing as that made by Mr. Matthaei of the cerebro-spinal and sympathetic systems, will be a credit to himself and to his teachers in any more purely medical study.

Will not Mr. Fleming approach his studies on the human brain with a more lively interest and a broader foundation for having dissected and drawn this frog's brain? The subject of human osteology will lose some of its proverbial dryness for Mr. Mueller since he has made his picture of the frog's skeleton and since he became familiar with the bones of the frog's cranium, some of which are no larger than the letters of this type. The myology of the human leg will have no terrors for Mr. Clapp who has so scientifically dissected and artistically represented the leg muscles of the frog. Mr. Grout will better appreciate the mechanism of a man's joints from having studied the appendages of a crayfish.

RULES AND REGULATIONS FOR ORGANIZATION AND MAINTENANCE OF THE SOUTHERN MEDICAL COLLEGE ASSOCIATION.

This Association shall be composed of delegates from Southern Medical Colleges, whose Faculties have signified a desire to become members thereof, signed these rules of organization, and paid the membership fee of $5.00.

The objects of the Association are to cultivate closer and more intimate relation between medical colleges and to elevate the standard of medical education by requiring a more thorough preliminary training and an increased length of medical study.

The Association shall be composed of one or more from each Medical College, belonging thereto, who shall be elected annually by their respective faculties. Each college shall be entitled to one vote in the transactions of the Association.

The officers shall consist of a President, Vice-President, Secretary and Treasurer, who shall be elected annually, just before the adjournment of the annual meetings, and shall perform the respective duties, pertaining to these offices in similar organizations.

The meetings of the Association shall be held at the same time and place of the meetings of the Southern Surgical and Gynecological Association, unless otherwise determined by the Association.

REQUIREMENTS FOR MATRICULATION.

Every student applying for matriculation must possess the following qualifications:

He must hold a certificate as the pupil of some known reputable physician, showing his moral character, and general fitness to enter upon the study of medicine.

He must possess a diploma of graduation from some literary or scientific institution of learning. or certificate from some legally constituted high school general Superintendent of State Education or Superintendent of some country Board of Public Education, attesting the fact that he is possessed of at least the educational attainments required of second grade teachers of public schools. Provided, however, that if a student so applying is unable to furnish the above and foregoing evidence of literary qualifications, he may be permitted to matriculate and receive medical instructions as other students, and qualify himself in the required literary departments, and stand his required examination as above specified, prior to offering himself for a second course of lectures.

The foregoing diploma or certificate of educational qualifications, attested by the Dean of the medical college attended, together with a set of tickets showing that the holder has attended one full course of medical lectures, shall be essential to attendance upon a second course of lectures in any college belonging to this Association.

BRANCHES OF MEDICAL SCIENCE TO BE INCLUDED IN COURSE OF INSTRUCTIONS.

Anatomy, physiology, chemistry, materia medica and therapeutics, theory and practice of medicine, pathology, surgery, obstetrics and gynecology, hygiene, medical jurisprudence, (forensic medicine) and special laboratory work as hereinafter provided.

QUALIFICATIONS FOR GRADUATION.

Candidates for graduation in addition to the usual requirements of medical colleges, must have attended three courses of lectures of not less than six months each in three separate years;

Must have dissected in two courses, and attended two courses of clinical or hospital instructions,

And must have attended one course in each of the special laboratory departments to-wit: 1. Histology and bacteriology. 2. Chemistry. 3. Operative surgery.

These requirements shall not apply to any student who has received a course of medical lectures prior to September 1, 1893.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES. . . . . 10 CENTS.
Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
NO. 68 WABASH AVE., CHICAGO, ILLINOIS.
All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, DECEMBER 3, 1892.

ORDINANCES OF THE AMERICAM MEDICAL ASSOCIATION.

The following preamble and resolution, adopted at the last meeting of the Association, should have been appended to those published in the issue of THE JOURNAL of November 19.

The action of the American Medical College Association at the meeting referred to by this resolution will be found on page 664 of this issue of THE JOURNAL.

WHEREAS, The Association of American Medical Colleges has adopted the following regulations, viz.: *Article III of the Constitution.*

§ 1. Members of this Association shall require of all matriculates an English composition in the handwriting of the applicant of not less than two hundred words, an examination by a Committee of the Faculty, or other lawfully constituted Board of Examiners, in higher arithmetic, algebra, elementary physics and Latin prose.

§ 2. Graduates or matriculates of reputable colleges, or high schools of the first grade, or normal schools established by State authority, or those who may have successfully passed the entrance examination provided by the statutes of the State of New York. shall be exempt from the requirements of Section 1.

§ 3. Students conditioned in one or more of the branches enumerated as requirements for matriculation, shall have time until the beginning of the second year to make up such deficiencies, provided, however, that students who fail in any of the required branches in this second examination shall not be admitted to a second course.

§ 4. Colleges granting final examination on elementary subjects to junior students, shall not issue certificates of such final examination, nor shall any member of this Association confer the degree of Doctor of Medicine upon any person who has not been first examined upon all the branches of the curriculum by the faculty of the College granting the degree.

§ 5. Candidates for the degree of Doctor of Medicine shall have attended three courses of graded instruction, of not less than six months each, in three separate years.

§ 6. *Students who have matriculated in any regular* medical college prior to July 1, 1892, shall be exempted from these requirements.

Resolved, therefore, That the American Medical Association most heartily endorses the efforts of the Association of American Medical Colleges to advance the cause of medical education, and demands of the medical colleges of the United States the adoption and observance of a standard of requirement which shall in no respect fall below the minimum standard of requirements adopted by the said college association.

SYMPHYSIOTOMY IN THE UNITED STATES.

A brief item on page 604 of the current volume of THE JOURNAL referred to the first recorded symphysiotomy in this country. The date of this operation was not there stated, but it was September 30, 1892. A second operation followed sharply after on October 3, in the University Maternity at Philadelphia. The obstetric surgeon in this second case was DR. BARTON COOKE HURST, who had the assistance and advice of DRS. NORRIS and HARRIS. The report of the case has appeared in the *Maryland Medical Journal* for October 29. The mother and child did well. The union of the symphysis took place promptly, and three weeks after the operation the mother was walking about the house as well and firmly as ever.

The patient was a primipara in this case as well as in the case of DR. JEWETT of Brooklyn (the first one), and the child of each was born living: unfortunately in the case of DR. JEWETT'S infant death took place about twenty-four hours after birth, from the prolonged compression to which its head had been subjected by its impaction in the contracted pelvis of the mother.

The technique of symphysiotomy will, under ordinary circumstances, be easy and void of complications. DR. HURST employed the curved knife Galbiati, one of the three at that time in the country. He at first thought that he would make the section of the symphysis with an ordinary probe-pointed, curved bistoury but he was glad to lay it aside and take up the Galbiati blade. In regard to the use of forceps in the delivery of the child, Dr. Hurst holds that it is not necessary to lay down any hard and fast rule—each case should be taken on its own merits and indications—but he will probably rely upon the forceps in his future cases as he did in his first one.

We judge that this operation has been properly re-introduced to the notice of the American profession and will receive a fair trial especially in our lying-in wards and hospitals.

NEW FORM OF IODINE TREATMENT FOR TUBERCULOSIS.

DR. RENZI has given, in the *Revista Clinica e Therapeutica*, some facts regarding his new method of employing iodine in phthisical cases. His formula prescribes the use of iodine one part, iodide of potassium, three parts, chloride of sodium, six parts, and distilled water 1000 parts. He injected this solution into the ear-vein of healthy, and also diseased rabbits, and into the subcutaneous tissue of rabbits, guinea-pigs and dogs. Having in this manner carefully established the complete tolerance of the compound, he began to give it to his phthisical patients. Hypodermatic dosage was first tried with them, as much as 100 grains having been thus given. This method was not well borne, and the remedy was next tried by the mouth, the dose being from 500 to 550 grains. Nineteen patients, nearly all of them with advanced phthisis, were thus treated. Symptoms of iodism were produced in some patients, but did not persist long after a discontinuance of the doses. In all these persons there was an increase of appetite and of body-weight. There was an increased flow of urine, the temperature was brought down to normal, and the number of bacilli in the sputa was diminished. The writer believes that the results obtained from this plan of using iodine will compare favorably with those of any of the other treatments that are at present in vogue.

HEIDENHAIN'S MICRO-TECHNIQUE.

The course of science is from the simple to the complex; and then again, the extension of science depends upon the adoption of the simpler for more intricate and complex tools and methods. Histology and pathology advanced with the perfection of the microscope and then rested until the microtome gave them a new impulse. We hear no longer of microscopists, but of microtomists.

The new impulse which FLEMMING and ALTMAN have given microtomy depends upon more perfect and successful methods of fixation and staining. These methods have been too difficult and the materials too unstable to permit of their general use. It is, therefore, with satisfaction that we read in the *Medical News*, of November 19, OHLMACHER'S recommendation of the simpler method of HEIDENHAIN.

This method is especially adapted to operators and physicians. The perfectly fresh tissue is cut in cubes no more than three-eighths of an inch square. It is fixed in a supersaturated solution of corrosive sublimate in water containing one-half per cent. of common salt. It must remain in this solution not more than an hour. It is dehydrated in 95 per cent. alcohol in the usual manner. Care must be taken not to leave it many days in alcohol as the tissue becomes too brittle to cut. It is imbedded in the usual manner and may be thus kept any length of time. The crystals of sublimate are removed from the sections on the slide by means of the tincture of iodine. This is again removed with alcohol. Any method of staining may be used.

Should this method be adopted in this country the author predicts great advance in the value of our histological and pathological studies.

PRIVATE ASYLUM FOR THE TREATMENT OF NEUROTIC DISEASE.

The rapid increase of the number of private asylums in this country, indicates a revolution in the methods of treatment. Dependence on locks and bars, and chemical restraint by drugs is giving away to surroundings and hygienic measures, adapted to suit the wants of each individual case. In England all private asylums for the insane and feeble-minded, are registered and under the control of the commissions of lunacy, who visit them, and require that they keep a record of all cases. In this country no public oversight is exercised, and the number and variety of such places depend on commercial wants and conditions, as interpreted by the owners and managers. The lunacy report of Great Britain for 1891, shows that the number of these asylums are eighty-six, and the number of patients is steadily increasing. For 1891 this increase was one hundred and eighteen patients. The suicides and injuries reported are much less than in other asylums, and the commissioners report that their management has been very satisfactory. In this country there are about fifty such asylums, including reputable sanitariums, or places under the control of regular physicians. Most of these are in New England and the Middle States and are managed by physicians who have had experience in public asylums as superintendents or assistants. Very little is known of their condition or management outside of the reputation of the managing physician. This is the only guide the profession has, and fortunately in most cases the physicians in charge recognize this, and use every means to stand well before the profession. As a rule, this class appeals to the medical public through its papers and discussions of the special topic of its work. There is another class whose extravagant pretensions and assumed results of treatment, with laudations of their means and methods, and superiority to others, are open to some suspicion. Extravagant advertisements, with circulars that have a familiar commercial ring that sounds unpleasant in scientific circles, are not uncommon to this class. A third class of asylums are managed by persons who are unknown to the profession, and who have no record or standing in the medical directories. Coming up suddenly from the unknown, they rely entirely on pretensions, and sooner or later disappear under a cloud of wrong doing. The pecuniary rewards of this field of medicine are less than in general practice, but the labor and exposure is also less, and the real scientific man has more time for study and reflection.

Nearly all the physicians in charge of such places have acquired a fascination for this field of labor in public institutions, and find it difficult to settle down to private practice, hence are compelled to take up this work. Others have a false impression that this is an ideal work, free from cares and labor, and rush into it only to be disappointed and drop out. The number of new asylums each year, and the number that die out and disappear, show that here as elsewhere, the "survival of the fittest" takes place. These places managed by good men, are supplying an increasing want that is becoming daily more apparent. These institutions should come under some control, or State supervision, and be registered and required to report their work; to submit to inspection, and come under some general rule of management and conduct. Then the medical public could have some guide and assurance, that all patients placed in them would receive rational and scientific care and treatment.

At present physicians wishing to place patients in private asylums, must make personal inspection of them or trust to circulars and statements before they can decide. If he has an inebriate patient, the number of empiric institutions that will claim to make a cure, will be bewildering. All this is wrong; while every physician has a right to open his house for the treatment and cure of his own private patients, when he extends the circle of his practice and receives strangers, he owes it to the public to come under some general supervision and make his means and methods known. The public demands that any one who receives sick and incompetent persons for treatment, should have some degree of capacity, both in scientific skill and surroundings to do this work. Private asylums have become a permanent necessity, but their value and usefulness are seriously periled by the empiric rivals who are starting up in every direction. A crusade against the quack asylums is a new field for reform, anxiously waiting for some pioneer to lead astruggle for the holy grail.

EDITORIAL NOTES.

Three Temperance Beverages.—From an English journal we copy the following suggestions for non-alcoholic drinks:

"Stokos is prepared thus: Put from 4 to 6 ounces of fresh oatmeal, ground as fine as flour, into a pan, mix with a little cold water to the substance of cream, then add 5 or 6 oz. of loaf sugar and a fresh lemon cut in thin slices with the pips taken out; add a gallon of boiling water. Stir thoroughly while the water is being poured on. Use hot, warm or cold. The lemon may be omitted or any other flavoring used instead. Costs 3d. a gallon, or five gallons 1s.; four lemons are enough for five gallons.

"Cokos is a good nourishing drink, made as follows: Put 4 oz. of fresh fine ground oatmeal, 4 oz. of cocoa, into a pan mixed with a little cold water into a thin batter, then add 6 oz. of sugar, pour on a gallon of boiling water (stir while water is being added). Take to the field in a stone jar. Costs 4d. a gallon.

"Hopkos is a good harvest drink: Boil ½ oz. of hops and ½ oz. of ginger (bruised) in 1½ gallons of water for 25 minutes; add 1 lb. of best brown sugar, and boil 10 minutes more; then strain and bottle, or put into a cask while hot; it will be ready for drinking when cold. It should be kept in a cold place. Dried horehound may be used instead of hops. Costs 3d. a gallon."

The inventor of "stokos, cokos and hopkos" is Mr. John Abbey, of Norwich, who says they have become quite popular with the crop-gatherers of 1892.

The "One Hundred Day" Disease.—Dr. Alice M. Ross, of Swatow, writes in the *Reporter*, October 8, that whooping cough goes by the name of the "hundred day disease" in Japan. That is a term that tallies fairly well with our own average prognosis, if we except those fortunate cases that are amenable to antipyrin or exalgine.

Hospital Nursing in Paris.—M. Laurent, of the Municipal Council, of Paris, is quoted by *The Lancet* as saying that the wages paid for nursing at the hospitals are altogether too small to attract the services of suitable persons. Those who become nurses are either saintly heroines or they are wrecks of humanity who cannot find employment anywhere else.

The "Medical Press and Circular."—This ever welcome London periodical, in its issue of November 2, states that a libel suit has recently been entered by the cancer-curer, Count Mattei. This is the second suit of the kind—the first having been that of our fellow citizen, Keeley—that has been thrust upon *The Press and Circular* by men outside the pale of rational medicine. In an editorial entitled "The Dangers of Honest Journalism," the writer regrets that the costs should be so heavy as they are, but he feels confident that these financial wounds will be healed by the approbation and support of the journal-reading part of the profession. But whether that shall be so or not, the editor proposes to keep his anti-quackery colors flying, claiming to be "the only British journal that is obnoxious to shams, and that has the courage to expose them." One other note-worthy point about this journal is the fact that it is not overloaded with a mass of indifferent material and does not cumber up one's desk and shelf room as do the larger and the so called "great uncut" journals. We wish *The Press* a happy issue out of its present and impending prosecutions.

BOOK REVIEWS.

The Student's Quiz Series. Practice of Medicine. A manual for students and practitioners by Edwin T. Doubleday, M.D., and J. Darwin Nagel, M.D. Philadelphia: Lea Brothers & Co.

This is an excellent little manual, arranged like its fellows in the form of questions and answers. It is based largely upon the works of Fagge, Niemeyer, Bennett, Flint, Delafield and Gowers. While we have heretofore expressed doubts as to the value of works of this sort, yet we can confidently recommend this work as one of the best of its kind. Especially do we commend that portion dealing with nervous diseases.

MISCELLANY.

Dr. John Ridlon has been appointed Professor of Orthopedic Surgery in the Post-Graduate Medical School of Chicago.

The Messrs MacMillan & Co. announce that the recently completed edition of Foster's Text-Book of Physiology in four parts is to be supplemented by the issue of an appendix on "The Chemical Basis of the Animal Body," by A. Sheridan Lea, Sc.D., F.R.S.

North Central Illinois Medical Association.—The nineteenth annual meeting of this Association will be held in the City Hall, Mendota, Ill., on Tuesday and Wednesday, December 6 and 7, 1892. The following is the general program:

Bacteriology, J. W. Edwards, M.D., Mendota. Discussion: H. Ziesing, M.D., Peru; T. W. Burrows, M.D., Serena.

Actinomycosis, T. C. Fenton, M.D., Streator. Discussion: B. S. Roseberry, M.D., Lacon; G. A. Dicus, M.D., Streator.

Nasal Polypus, L. G. Thompson, M.D., Lacon. Discussion: J. H. Coulter, M.D., Chicago; A. E. Owens, M.D., Princeton.

Some Clinical Experience in the Treatment of Diphtheria, Harriet E. Garrison, M.D., Dixon. Discussion: E. T. Goble, M.D., Earlville; C. E. Davis, M.D., Peoria.

Diphtheria and Its Treatment, C. D. Chalfant, M.D., Streator. Discussion: L. R. Burns, M.D., LaSalle; Jas. Tweddale, M.D., Washburn.

My Symptoms, Feelings and Impressions During an Attack of Metastatic Rheumatism of the Meninges of the Brain, J. S. Whitmire, M.D., Metamora. Discussion: J. C. Hathaway, M.D., Ottawa; T. H. Stetler, M.D., Paw Paw.

The Relations of Physicians with County Coroners, E. J. Carroll, M.D., Somonauk. Discussion: J. T. Milling, M.D., Peru; W. A. Mansfield, M.D., Metamora.

Typhoid Fever, J. Stout, M.D., Ottawa. Discussion: J. D. Scouller, M.D., Pontiac; F. M. Pendleton, M.D., Magnolia.

Our Present Knowledge of Epilepsy, R. Hemala, M.D., Onarga. Discussion: J. W. Pettit, M.D., Ottawa; C. E. Fogg, M.D., Lowell.

Tenotomy in Antero-Lateral Spinal Sclerosis, J. A. Freeman, M.D., Millington. Discussion: G. A. Zeller, M.D., Peoria; I. H. Reeder, M.D., Lacon.

Therapeutical Uses of the Coal Tar Preparations, F. C. Robinson, M.D., Maywood. Discussion: G. F. Schreiber, M.D., Wyanet; D. S. Jenks, M.D., Plano.

Volunteer Papers.

The S. D. Gross Professorship of Pathological Anatomy Fund.—The Committee appointed by the General Committee to audit the account of Dr. Richard J. Dunglison, Treasurer of the S. D. Gross Prosessorship Fund of the Alumni Association of Jefferson Medical College, respectfully report that after an examination of such account they find that there were sixty contributors to the fund, the total amount contributed being $3,499 00. In accordance with a resolution of the General Committee these contributions have all been returned to the donors, and the Treasurer has presented a voucher for each amount thus refunded. A great portion of the whole amount has been retained undistributed until recently, so that the interest on the amount might so accumulate as to enable the Committee to refund to each subscriber the full amount of his contribution, without any deduction for expenses of publication of circulars, postage, etc., which were necessarily heavy, from the widespread diffusion given the objects of the Fund.

The names and addresses of the subscribers and the amounts contributed by them are as follows:

Dr. S. D. Gross, Philadelphia, Pa	$1,000 00
" J. Marion Sims, New York, N. Y	500 00
W. L. Conyngham, Wilkes-Barre, Pa	200 00
Dr. Hunter McGuire, Richmond, Va.	125 00
" Joseph Hearn, Philadelphia, Pa	100 00
" Albert H. Smith, Philadelphia, Pa.	100 00
" N. Bozeman, New York, N. Y.	100 00
Henry C. Lea, Philadelphia, Pa	100 00
Dr. T. Addis Emmet, New York, N. Y	100 00
" N. Senn (Collections) Milwaukee, Wis	63 00
" J. B. Weever, Mount Vernon, Ind	50 00
	$2,438 00
Brought forward	$2,438 00
Dr. J. M. Barton, Philadelphia, Pa.	50 00
" P. S. Conner, Cincinnati, O.	50 00
Mrs. Elizabeth Casey, Ballston Springs, N. Y.	50 00
Dr. L. Turnbull, Philadelphia, Pa	50 00
" R. A. Given, Burn Brae, Pa.	50 00
" A. Stillé, Philadelphia, Pa	50 00
" R. Douglas, Nashville, Tenn	50 00
" J. Solis-Cohen, Philadelphia, Pa	50 00
" J. W. Holland, Philadelphia, Pa	50 00
" L. D. Wilson (Collections) Wheeling, W. Va.	45 00

Total	$3,499 00

J. Ewing Mears, M.D.,
William B. Atkinson, M.D.,
Auditing Committee.

Philadelphia, October, 1892.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from November 19, 1892, to November 25, 1892.

First Lieut James D. Glennan, Asst. Surgeon U. S. A., is granted leave of absence for one month.

Major John C. G. Happersett, Surgeon U. S. A., is granted leave of absence for one month, on surgeon's certificate of disability, with permission to leave the limits of the department.

A board of officers, to consist of Col. Joseph R. Smith, Asst. Surgeon-General U. S. A.; Major David L. Huntington, Surgeon U. S. A.; Major Benjamin F. Pope, Surgeon U. S. A., is by direction of the President, appointed to meet at Whipple Bks., Ariz., on Monday, November 28, 1892, or as soon thereafter as practicable, for the examination of Capt. Louis M. Maus, Asst. Surgeon, with a view to determining his fitness for promotion, as contemplated by the Act of Congress approved October 1, 1890.

Capt. L. W. Crampton, Asst. Surgeon U. S. A., is granted leave of absence for one month, with permission to apply for an extension of three months.

Major Calvin De Witt, Surgeon U. S. A., is granted leave of absence for one month, with permission to apply to the proper authority for an extension of one month.

Capt. W. W. R. Fisher, Asst. Surgeon U. S. A., leave of absence for seven days granted is hereby extended fourteen days.

ORIGINAL ARTICLES.

DIET IN ITS RELATION TO THE TREATMENT AND PREVENTION OF DISEASE.

Read before the Section of Physiology and Dietetics at the Forty-third Annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY AUGUSTUS P. CLARKE, A.M., M.D.,
OF CAMBRIDGE, MASS.

The study of dietetics from the earliest ages among people of different nations that have cultivated the art of medicine has often been an important subject for consideration. Thus, in the Hippocratic Treatises mention is made of diet in health as well as in disease. In the treatment of certain fractures the ancients had different grades of diet, as the full, the ordinary, and the low. The diet was sometimes restricted; food that was of a laxative character was not unfrequently employed. Abstinence from flesh and from wine was often enjoined; in such cases a more nourishing diet was gradually resumed. The aphorisms of Hippôcrates embody many regulations respecting diet. A slender and restricted diet in chronic disease was regarded by Hippocrates as always dangerous. In the more acute diseases an attenuating diet was used. From the writings of the ancients it is evident that they attained to a high degree of knowledge as regards the influence which food exercises in health and in disease. Such knowledge obtained was a natural sequence of the manner of their living. As those nations advanced in the upward scale of civilization the arts multiplied, commerce extended and wealth so increased that the pleasures in living became numerous and far-reaching. The accounts of the excesses indulged in at the table even when placed in comparison with some of the more modern customs seem almost incredible. The praise which Cicero bestowed on his host for the thoughtfulness in providing him an emetic to be taken before the feast was served, has become proverbial. Luxurious tables during the ascendency of Rome were not limited to the confines of that mighty capital, but were often abundant in the more distant parts of the empire. During a recent visit to the excavations made at Pompeii and at Herculaneum I became interested, not only in many articles and utensils taken from the ruins, but also in the evidence of comforts and luxuries which wealth afforded to many of the inhabitants of those cities, which were buried by the eruption of Vesuvius. M. Monnier[1] has given a good account of one of the suppers, taken from a bill of fare found at Pompeii. This bill of fare found in the ruins was well preserved. The menu was taken from the house of Paratus, not an emperor but a citizen, who of course, indulged in only a mere modest repast.

First Course.—Sea urchins, raw oysters at discretion, pelorides or palourdes (a sort of shell fish now found on the coast of Poitou, in France). Thorny shelled oysters, larks, a hen pullet with asparagus, stewed oysters and mussels, white and black sea-tulips.

Second Course.—Spondulæ, a variety of oysters; sweet water mussels; sea nettles, becaficoes; cutlets of kid and boar's meat; chicken pie; becaficoes again, but differently prepared, with an asparagus sauce; murex and purple fish. The latter were but different kinds of shell-fish.

Third Course.—The teats of a sow *au naturel*, they were cut as soon as the animal had littered; wild boar's head (this was the main dish); sow's teats in *a ragout;* the breasts and necks of roast ducks; fricasseed wild duck; roast hare, a great delicacy; roasted Phrygian chickens; starch cream; cakes from Vicenza.

The deglutition of all these was assisted by frequent draughts of wine made in the vineyards planted on the slopes overhanging the walls of Pompeii. This wine was often of a light grade, was of fair quality and if sterilized could be kept for many years. Illness from over-indulgence or from errors in diet was not unknown to the Pompeians. From what has been discovered in the ruins at the house of the surgeon, and also in the ruins at the shop of the apothecary it becomes evident that this ancient people often sought for relief from maladies and from functional disturbances induced by disregard of those fundamental principles which, had they been observed would have led to much higher degree of health. Temperature of food which has been served is an important subject for consideration. Food when heated to a high degree may at first act as a stimulant but will nevertheless cause an undue contraction of the arterioles. This condition of the capillary circulation will cause a diminution of the flow of the fluids necessary for digestion, will lead to gastric anæmia and to the occurrence of certain forms of dyspepsia. My own professional experience, however, justifies me in making an urgent plea for regular ingestion of warm food, which not only conserves the resources of the stomach, but also overcomes the tendency to the indulgence in those stronger stimulants, the use of which so often results in physical as well as moral degradation. Dyspepsia and indigestion before the occurrence of marked organic lesion can almost invariably be cured by a rigid adherence to a regulated diet. All foods should be thoroughly masticated. Fermentable articles should in great measure be avoided. In this list may be included certain starches, sugars and sometimes fats. It is often, however, observed that many kinds of food which are seemingly ill-adapted to a dyspeptic may be wholly innocuous when taken singly and in moderation. Thin soups and allied articles have in my practice been the best adapted for a cure; raw oysters are often beneficial, though I believe the nutritive properties of this class of food have been overrated.

---

[1] "The Wonders of Pompeii," by M. Marc Monnier, p. 161.

The lighter grades of meats, such as mutton, lamb, game, venison, and poultry are to be preferred to the meat furnished by the butcher. Eggs, when poached or boiled, are to be recommended. Eggs beaten or whipped up with water or with wine are not as good on account of the danger of the admixture of atmospheric air. Farinaceous articles, including stale bread, tapioca, sago, corn bread, rice, hominy, macaroni, crackers of different grades, cream and butter are also to be recommended. Certain fruits and vegetables are often required by the dyspeptic. In this list may be introduced apples, when baked, grapes, oranges, peas, spinach, asparagus, celery, lettuce, string beans, and peas, occasionally dandelions and chicory. In cases in which the patients are of a plethoric habit, cold water may be drunk half hour before each meal. In those cases in which the persons are of nervous temperament or are anæmic, water of the temperature of 110° F. to 120° F., should be taken in preference. The dyspeptic should scrupulously avoid partaking largely of articles of food that have been hardened in the preparation of cooking, or of articles that are rich or have been so highly seasoned, or have been prepared in such a manner as to render them difficult of digestion. Such articles should be avoided, not only on account of their giving rise to immediate disturbances, but also on account of their leading to an inflammatory condition of the mucous and glandular tissues, and to debility and atrophy of the structures entering into the organs essential to production of the digestive process. Closely connected with the consideration of food adapted for gastric disturbances is the consideration of food for renal affections. In the treatment of uric acid diathesis, notice must be taken relative to the habits and occupation of the patient. In a case in which the patient is habitually engaged in literary pursuits food containing some of the protein elements will often be indicated. An azotized aliment to a limited extent must be allowed. Food consisting largely of the farinaceous element will suffice for the invalid who is able to take prolonged and regular exercise, such as mountain climbing, riding on horseback, gardening and farming, and manual labor generally. Certain forms of carbo-hydrates, however, such as wine, fermented liquors, and perhaps most of the alcoholic preparations, should be excluded in a large number of cases which occur in the different kinds of renal disease. In cases of excess of urates, or in lithic diathesis, a diet abounding in alkaline salts must be employed. For in such cases there will be found in the blood insoluble uric acid the presence of which can be safely overcome only by the proper administration of food. In cases of chronic nephritis, in which the urine voided is excessive in quantity and is more or less albuminous, milk usually agrees well and should be freely taken. Water which has been sterilized should also be taken in liberal quantities. Most of the articles of diet mentioned as suitable for cases of dyspepsia will often be found beneficial in the management of the diet for this form of renal disease. In the treatment of obesity a diet composed largely of animal food has often been recommended. My own professional experience leads me to oppose such a method of procedure. In a case in which the food is limited to a meat diet there is apt to occur an excess of urea. In the case of G., aged 48 years, and whose weight was three hundred and fifteen pounds, an attempt to effect reduction of weight by diet, consisting in great measure of rare beef, roast mutton, boiled ham and stewed veal, each taken on different days, was undertaken by direction of his physician. After a year's experience on this routine course, the patient applied to me for treatment of an attack of gravel. He had begun to pass from the bladder small calculi of uric acid. Under my treatment the use of all kinds of animal food was immediately discontinued; a plain, vegetable diet with milk and gluten, eggs, fish, with some fruits, and sterilized water were prescribed. The patient gradually improved. The sediment of the urine disappeared. There were fortunately no gastric disturbances. Within one year the weight had materially diminished; the morbid craving which had been engendered for animal food was completely overcome. The patient regarded himself as in sound condition; he was able to take long walks daily without becoming fatigued.

In this connection I cannot refrain from remarking that the substitution of animal diet exclusively for a mixed diet or for one composed in great measure of the lighter fruits, vegetables, together with a small amount of eggs, milk, fish, and other articles whose waste products are easy of elimination, for persons suffering from excessive obesity is according to my experience, a most pernicious method of procedure. This leads to the consideration of diet for those who suffer habitually from the rheumatic diathesis. In the management of such cases one should not loose sight of the important relation subsisting between the ingesta and the egesta of the human organism. In many cases of troublesome rheumatic symptoms the digestive function is apparently well performed. In such cases the patient over-eats because he feels weak; not because he has not taken an adequate amount of nourishment, but because there has been a failure on the part of the eliminative organs in excreting the surplus material which has been taken into the stomach, been carried into the circulation and finally has been deposited among the tissues and organs of the body. In the treatment of this class of cases a radical change in diet has often to be made. All articles of food that have a special tendency toward the elaboration of the biliary principles and also of the urea should be wholly excluded for a long time from the diet list.

That form of renal disease occurring in the female when pregnant should always demand our greatest solicitude. The food allowed to be taken by such a patient should always be light and easy of digestion. In the treatment of this class of cases I have invariably found that all butcher's meat should be interdicted. In the case of Mrs. S., who in her first confinement had convulsions precipitated by renal complication, food composed largely of animal diet had been prescribed up to the very hour of the onset of labor. I was not called to this case until labor had begun. The convulsions were fortunately overcome; she was kept afterwards on milk and farinaceous articles to which eggs and fresh fish were frequently added. In her second pregnancy renal trouble was of the mildest type; labor was accomplished without the occurrence of eclampsia. During the third pregnancy she was not under my care. The directions which I had heretofore enjoined regarding the diet were not carried out; the convulsions appearing in that third labor evidently in consequence of the re-occurence of the renal complication, I was assured were the immediate cause of death. In my own practice I have notes and reports of several other cases in which renal disease brought on or hastened by pregnancy, was practically cured or overcome by the strict intervention of light but nourishing diet from which animal food of every description had been excluded.

Although our knowledge regarding the original cause of the appearance of cancer is as yet meagre still some evidence by clinical experience has been offered that this disease is not wholly uninfluenced in its origin and course by diet. My first impressions that cancerous affections would be influenced by diet were received from my late Professor, Dr. Henry I. Bowditch, who mentioned to me the case of an eminent physician. It seems that a cancerous growth appeared on the face of the physician. This led him to consult prominent surgeons in regard to the advisability of its removal. A decision against the safety of a resort to surgical measures prompted the sufferer to consider more carefully the influence the particular articles he had been accustomed to use in the diet list for his own use. His diet had always been a most generous one; he therefore began to suspect that it had exerted material influence in the causation of his disease. Suffice it to say. that the change from full diet to one that was radically different but opposite in its character, exercised a most important influence in affecting a retrograde action of the disease. Though evidence has been afforded that cancer in some of its various manifestations is contagious, it is also important to observe that its occurrence so common in the uterine tissue after the menopause and for sometime afterward indicates that the structures of that organ are favorable soils for its development. The adaptation of the uterine tissues at this particular period further indicates that these favoring conditions are dependent on accidental circumstances.

When the tissue is in a normal state the regular recurring catamenia no doubt do attenuate and finally discharge any germs that gain entrance into those parts. After the cessation of the catamenial flow, the uterine cervix or body undergoes in histological structure such important changes that the tissues become to a certain extent culture chambers in which disease germs gaining admission may develop. The proneness of these tissues to disease is more particularly enhanced when the nutritive forces determined to the genital tract are no longer expended through the agency of the menstrual molimen, but are retained and as it were stored and unemployed. These tissues for a while at least, become obnoxious to the growth of germs, bacilli, or to certain bacteria. By lessening the currents of nutritive force distributed to the tissues of the organism we modify, or starve those embraced within the area of the uterine zone, and render them less prone to the invasion of bacterial and of adventitious elements. In three cases of uterine cancer treated almost from their inception, principally, by careful management of the diet I am satisfied that the disease was practically extinguished. In a fourth case to which I was called, had I had the good fortune to commence earlier or at least had been able to carry out more regularly and systematically the management of the diet that was indicated, I feel confident a successful issue would have been accomplished or an important modification in the results of the invaded tissues would have been effected. The facts observed in the above cases are of course, too few for establishing any general conclusions, though they suggest the importance of further observation. In the treatment of phthisical cases, though oysters, eggs, fish, cream, butter and many of the milder fats are beneficial, I have nevertheless found in my own practice, that a diet composed largely of animal food is the one best adapted for staying the progress of the disease or in the earlier stages for hastening the cure. In some phthisical cases in which the digestive organs were in healthy condition I have advised the ingestion, of large quantities of beef. mutton, fish, fowl or game. In some cases I have recommended the almost daily use of venison; in this aliment I include the flesh of the cariboo. In some cases wonderful results have been accomplished. By this method of treatment in one case occurring in a man aged thirty-two years, I was able to check the disease and to do much toward effecting cicatrization of the lung tissue, even after the occurrence of repeated attacks of profuse hæmorrhage and after a large cavity had formed in the superior lobe of the left lung. At the time I commenced the treatment the patient was in very feeble condition; he was expected to live only a very short time. By means of the treatment persistently carried out he survived for fifteen years. The patient died at the age of forty-six years, of double pneumonia which lasted but a few days; the fatal attack was brought on by a prolonged exposure during the season of influenza in the month of January, 1889. Autopsy revealed an extreme atrophy and contraction of the upper lobe of the left lung; much of the lung tissue of that portion had disappeared. The left bronchus was dilated; there was still the remains of a cavity into which small pockets opened. The lower portion of the left lung was fibrous and contained but few air vesicles. The cavities opening into the bronchial tube were lined by a secreting membrane. Some fluid was found in each of these cavities. The left lung had been in great measure rendered useless. The right lung was enlarged. All the lower portion was heavily congested, presenting the early stage of acute pneumonia. On the right side above there was only a limited portion which was pervious to air, This condition of the lungs during the last hours of life was the cause of the extremely rapid respiration, which varied from forty to eighty per minute. Both lungs were densely adherent. The heart was enlarged and dilated. The cardiac valves were, however, normal. The kidneys were healthy; the liver was enlarged, but otherwise healthy; the spleen was normal, so also were the intestines and stomach. The patient had from time to time expectorated large quantities of catarrhal and purulent exudation. Before the fatal attack the patient had been gradually improving. The sputa which I examined according to the method of Professor Koch, of Berlin, revealed but few characteristic bacilli tuberculosis. The otherwise good condition in which the patient had been kept by the rich and nourishing food prescribed, finally overcame essentially the influence of the bacilli, or at least prevented them in large measure from gaining entrance into the system. In this connection I should say that the patient's condition was not left wholly to the influence of dietetic treatment; his urgent symptoms often demanded prompt administration of the most effectual remedial agents. I am confident, however, that the great success in his case would not have been achieved unless the special attention had been paid to the consideration of dietetic measures. In prescribing a diet, consisting so largely and generously of flesh, much study and consideration should be given in determining in any case the soundness, capability and endurance of those organs which are concerned in digestion and in elimination. The condition of the kidneys above all should from time to time be inquired into. The autopsy in the case here reported shows that the kidneys though heavily worked remained sound until the last.

The enlargement of the liver, which in this particular case acted as a diverticulum was rather the result of a conservative process than as a pathological one. The enlargement of the heart was by no means found to be a serious complication; it occurred doubtless in consequence of the excessive work which that organ was called upon to perform in propelling the blood through the affected pulmonary tissue; this increased action of the heart was fast accommodating itself to the new order of things. Judging from the whole history of the case from its inception until its close it is evident that the most liberal and nourishing diet which had been advised and which the patient was so well able to bear, would, had he not suffered from the accidental exposure, have resulted in a restoration to health or would have prolonged his life to many more years of usefulness and enjoyment. As it did result the patient had been enabled during the years while under my care to achieve by honorable mercantile pursuits a substantial fortune for the maintenance of his family. The dietetic treatment best adapted for phthisical cases can accurately be determined only by a careful consideration of each of the several factors present in any individual case.

In some cases milk is a most useful article of diet; sometimes it may be taken cold, and even in large quantities. Some patients, however, are unable to take milk in this way; such patients may take milk if given in small quantities when given at the temperature 100° F. or at a temperature somewhat above that point. Peptonized milk can often be taken with advantage; eggs, fish, fowl will sometimes prove to be most nourishing articles for the phthisical patient. In cases in which there is but little tendency to diarrhœa, I have found green vegetables of much service. In the treatment of phthisical cases, in which the greatest success however, is to be expected my experience proves that articles of diet largely nitrogenous in character must be ingested. In carrying out the treatment for this latter class the carbohydrates embracing oleaginous and fatty substances may to a certain extent be added; at intervals more or less remote those articles formerly classed as feculaceous in their immediate principles may not unadvantageously be employed.

A HARD STATE TO PRACTICE IN.—The Alabama State Medical Examining Board rejects 41.16 per cent. of candidates who apply for license.

EPITHELIA.

Read by Title in the Section of Physiology and Dietetics, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY EPHRAIM CUTTER, M.D., LL.D.,

OF NEW YORK.

These are morphological elements of mucous, synovial and serous membranes, and take their name from epi, upon, and tithemi, to place, and mean placed upon.

They are cells with protoplasmic contents. There are three kinds as to shapes: 1. Pavement. 2. Cylinder. 3. Ciliate.

Their seats are as follows:

Pavement or Tessellated Epithelia.—Besides the above named seats they are found upon the skin, hair follicles, nails and toe matrices, on the membranes of the aqueous protoplasmic humor, the choroid, the capsule of the lens, the retina, the conjunctiva of the ball of the eye, the cavity of the tympanum, the lower half of the pharynx, the œsophagus, the endocardium, some veins, the capillaries, all glands and ducts. the vagina and female urethra, the bladder, uterus, kidneys, pelvis and tubules.

In the arteries and many veins they are spindle-shaped.

Cylinder Epithelia.—In mucous membranes, in Lieberkuhn's follicles, all the ducts of the glands of the alimentary canal, in the lachrymal and the mammary glands, the male urethra, the vas deferens, the vesicular seminales, the prostatic ducts, the Cowper's and uterine glands.

Ciliated Epithelia Seats.—The larynx, trachea, bronchi, nares, pharynx above the level of the base of the nasal bones, the antra, the frontal sinuses, the inner surface of the membrana tympani, the Eustachian tubes, the uterus, the Fallopian tubes, the lachrymal sacs, nasal duct, palpebral conjunctiva—or that which is on the under surface of the eyelids and ependyma (Micrographic Dictionary). This list is complete enough for our purpose. Never does a human being wash hands or body, defecate, urinate, vomit, expectorate, sweat, bleed, conjugate or rub the body surface, unless there is a separation of multitudes of epithelia from that body. Hence we may infer that epithelia have a prodigious part to play in the physiology of the human body.

Shapes.—These have been indicated already, but besides the pavement, cylinder and ciliated cells, there are the caudate, spindle-shaped, hexagonal, oblong, lozenge-shaped. The situation varies the shape. For example, in the liver they are found hexagonal.

Contents.—Independent of their products, clear and structureless protoplasm, that first plastic material which is the basis of all the organized tissues and products in the human body. Protoplasm is a field on the confines between man and God the Creator. Man cannot tell why one cell secretes bile, another milk, another wax, another fat, another pigmentine, any more than he can tell why gold is yellow or silver white, or air is blue.

Those who believe in God explain these differences of protoplasm, metals or air, by referring them to the will of God. Those who say they are so by nature mean the same thing, as the word "nature" implies something born from "God" as a source of birth. Those evolutionists who deny God, I believe, have not explained the reason why epithelial protoplasm is so varied in its production according to the needs of the body and being evoluted by those needs. Needs do not always develop the means of supplying these needs, as taught by evolutionists. If so, there would be no protested notes, no one would starve for want of food, nor drown for want of air; no babies would die for want of good *breast-milk*, the product of epithelial protoplasm.

Autonomy.—Epithelia have an independent existence over the other tissues of the body. They will take up some substances and refuse to take up others, thus showing the power of election. To be sure this is seen in inorganic substances, as in chemistry. They exist after death of the body, or after separation from the body. Ciliated epithelia will long wave after death of the body systemic.

Surgery has taken advantage of this autonomy by the process of skin grafting, whereby skin epithelia are clipped from the sensitive body, causing hard pain and sacrifice. The method of skin grafting originated by Dr. C. B. Kibler, of Corry, Pa., shows still more prominently the autonomy and stability of dermal epithelia. He scrapes off the epithelia from the palmar surfaces of hands and feet and from callouses, keeps them dry an indefinite time ready for use, and finds that they are as good as the epithelia from sensitive skin; their vitality is like that of teeth. It is hoped that there will be no more useless martyrdom in skin grafting after this.

Those who study the morphology of potable waters know how abundant epithelia are. While they are not all human, some of them must be, and their vitality must be great to stand the continued soaking they get and to resist decomposition.

Another evidence of epithelia autonomy is in the secretions. We have alluded to the bile and milk epithelia. Besides these are wax, fat in its varied forms, sweat, mucus, urinary liquids, salts, pancreatic, gastric and intestinal juices, to name no more, and these are originated by the epithelia from the blood; and to repeat, man knows no more how these secretions are made than he knows the process of decomposing carbon dioxide gas, the evolution of oxygen, the appropriation of carbon, the production of resin, balsam and oils, going on in the leaves of the trees right under his eyes and over his head. Some time man may know the secret, but it will be some time yet. But for these different products of epithelia, life could not go on.

The mechanical functions of ciliated epithelia show autonomy also by removing secretions from their sites, because the power is applied towards the outlet. Otherwise, for example, the lungs would be clogged; this would happen if the epithelia forced the secretions towards the terminal tubes and air cells, and death would result. Dr. B. W. Richardson, of London, gives in the *Asclepiad* a graphic account of "Default of ciliary action" in the air cells, or rather air passages, especially during fogs moist and dry. He says ciliary action runs with age; most active in youth, good in middle age, and probably ceases altogether in very old age. The morphology of the air is well collected by the ciliated epithelia of the air passages, and is included in the morphology of the sputum. Those who live in cities are little aware of the immense amount of material there is in the atmosphere coming even from meteoric bodies, volcanoes and coal dust, and frequently from other worlds.

The ciliated epithelia of the nares are very useful to clear the respired air of these passing bodies. Now the motion of the cilia is something marvellous; it is protoplasmic. Muscular motion is protoplasmic, as the automobile motion of the bodies of the bacteria of fermentation or of monads which act on diatoms, for example, as tugs do on ships. As we refer the motion of bodies celestial and terrestrial to the power of the Creator, so must we see in the said motion of cilia towards the outlet of their cavities only another evidence of His marvellous work. Certainly ciliary motions are those of vital energy. It has been said by another that epithelia grow by feeding, organize their food into new epithelia and secretions, throw off fæcal matter, and that their work is independent, like an individual organism. Another has also broadened this idea, that the intense disturbance that comes in disease to epithelial cells is a cause of rise in temperature, *i. e.*, fever. I think there is great truth in this view. Certainly epithelia have a tremendous work to do to cast out offensive or noxious substances, and if they are automatic, is it unreasonable to suppose that they get excited and hot in those efforts, just as one would in trying to expel an intruder from home at night who does not want to go until he has done his mischief and stolen his prey.

Effect of Nerve Forces on Secretions.—The effects of the nerves on epithelia are wonderful. Some mothers think that their breast milk is formed while they are suckling. If this is so, the epithelial activity must be something marvellous.

Tulchen.—The Dutch kill a calf and stuff its skin so as to resemble the live animal. This is called a "tulchen," and is placed while the mother is milked just so that she can see it in a position of suckling; the result is that she lets down her milk and a larger quantity is obtained than otherwise would be. Maternal affection thus influences the production of milk and hence influences the work of the protoplasm of the epithelial cells. In India this tulchening has been done for ages, as a late authority states.

A Cow's Jealousy.—Mr. C. H. Brown, in *The London Spectator*: "A few years ago I had a quiet milch-cow, 'Rose,' which certainly was fond of Thomas, the man who milked her regularly, and she also showed an aversion to dogs even greater than is usual in her species. One night, for what reason I now forget, I had tied up a young collie dog in the cow-shed where she was accustomed to be milked. The following morning I had just begun to dress when I heard the puppy barking in the cow-shed. 'Oh,' thought I, 'I forgot to tell Thomas about the puppy, and now the cow will get in first and gore it.'

"The next minute I heard a roar. I dashed down to the spot, and at the same moment arrived my son, pitchfork in hand. There lay Thomas on his face in a dry gutter by the side of the cow-shed, and the cow butting angrily at him. We drove off the cow and poor Thomas scuffled across the road, slipped through a wire fence, stood up and drew breath. 'Why Thomas,' said I, 'what is the matter with Rose?' 'Well, sir,' said Thomas, 'I heard the pup bark and untied him, and I was coming out of the cow-house with the pup in my arms when Rose came around the corner. As soon as she see'd the pup in my arms she rushed at me without more ado, knocked me down and would have killed me if you hadn't come up.' Thomas had indeed had a narrow escape his trousers were ripped up from end to end, and red marks all around his legs showed where Rose's horns had grazed along them. 'Well,' said I, 'you had better not milk her this morning, since she is in such a fury.' 'Oh! I will milk her right enough, sir, by-and-by; just give her a chance to settle down like. It is only jealousy of that ere pup, sir. She could not abide seeing me a-fondling it.'

"Well, as you like,' said I, 'only take care and mind what you are about.' 'All right, sir.' In about twenty minutes Thomas called me down to see the milk. The cow had stood quiet enough to be milked. But the milk was deeply tinged with blood, and in half an hour a copious red precipitate had settled to the bottom of the pail. Till then I doubted the jealousy theory. After that I believed."

As there is no Section of Pathological Anatomy in this Association, it may not be out of place to briefly sãy that dermal epithelia are invaded by vinegar yeast in consumption. Specially they are invaded in small-pox, measles, scarlet fever, diphtheria, etc.

Epithelia degenerate into fat in Bright's disease of the kidneys.

As said by another, they may also be paralyzed or made drunk, as it were, by carbon dioxide gases, so that they do not distingush as in the natural state, and they take in noxious substances which are transmitted into the lungs, for example in consumption. First there is consumption of the bowels, and next follows consumption of the lungs. In cases where the epithelia refuse the passage of the mycoderma aceti or vinegar yeast, the case remains consumption of the bowels. This is the most clear explanation I know, of consumption of the bowels.

Epithelia are extensively thrown off in Asiatic cholera, as I early observed, in all stages of formation, and perhaps this explains the great prostration in those cases.

Deformed Epithelia.—There is no doubt that epithelia are deformed, and that very little notice of this feature has been made. But there is a relation of deformed ciliated epithelia to grippe which is an important one, for it is widespread over the globe, and for its severity specially in complicating other diseases, as lung fever, bronchitis, pleurisy, etc. To be sure some take the view that the forms called by the great majority of physicians deformed ciliated epithelia are not epithelia at all, but are cilio flagellated infusoria which infest the air passages in grippe, and make under the microscope one of the most beautiful and wonderful displays of protoplasmic life to be seen.

So long as man is infected by animal parasites, as tænia, scabies, guinea worms, ticks, lice, microbes, etc., it is nothing strange to have them infected by an infusorium which is communicated through the air from man to man. But concede this to be only deformed ciliate epithelia, then the following things must be explained:

1. Why is it that when grippe patients are found with thirty to forty living and moving forms, which my critics call deformed ciliated epithelia, in the excretions of the air passages, they suffer so much from nasal, pharyngeal and laryngeal irritation, coughing, sneezing and expectorating freely, with flushed countenances looking like lung fever, and yet when the fumes of burning sulphur, nascent chloride of ammonium or atomized benzoate of soda are haled, great relief is afforded in a few moments? Then why, on examining the excretions, are the forms found dead and motionless?

2. Are we then to infer that deformed ciliated epithelia alone are sources of irritation alive, but dead they are not sources of irritation? If so, then there is a new law that dead tissues do not irritate, but live ones do, contrary to common sense.

3. If I find a man sick with incessant coughing, which has resisted all medication; if the expectoration shows what my critics call deformed ciliate epithelia protoplasm in action; if I present burning sulphur and if I find the cases cured thereby, am I to infer in these cases also that live tissues irritate, and when dead do not?

4. I have stated that I did not know that ciliated epithelia were found in the ocular conjunctiva; but they have been found in the palpebral or eyelid conjunctivæ. Still I think it is possible that all the forms found were not ciliated epithelia, after making this allowance.

Stomata.—These stomata were beautifully shown in the microphotos of the late Surgeon Woodward, U. S. A. These are openings between the endothelia of capillaries and veins. In inflammation they open and allow the migration of white corpuscles, which have a habit of breaking up into two, three, four, five or six parts and then reuniting. When escaped outside the blood-vessels they coagulate in a collection, forming what we call abscesses.

The stomata must play an important part in inflammation by affording egress to the white corpuscles, though in health it is thought doubtful if there is any such egress. In this the animal differs from the vegetable stomata, as found in leaves, which afford ingress for carbonic acid gases from animals, and egress to the oxygen into the atmosphere to us.

Hair and Nails.—The epithelia of the skin take curious modifications in the production of hair and nails. The vitality of hair is wonderful and lasts after death for a long while. I once saw a man place the hair of his daughter's head, who had been buried for ten years and was exhumed for a new cemetery lot, on the top of a common flour barrel and it reached to the floor. I was told that in her last sickness her hair had been cut short. This positive instance, it seems to me, settles the question of hair growing after death, in this case at least. After this I was prepared to believe that the horses and men who had been killed in battle, buried in a trench and exhumed by an earthquake in Chili, had had the hair grow after death.

The fact that hair varies in the sexes shows a wonderful control of epithelial power on the part of our Creator. So the nails are constantly being reproduced by the epithelia of the matrices at the root of the nails, and all the time under our eyes forming compact, dense, transparent-like bodies much like the cornea, for a useful purpose just when they are needed. They are one of the best tests of the nutrition of the body. If thin, ridged with longitudinal furrows or with deep transverse furrows, you may be sure that something has interfered with the body nutrition, or you may be dealing with a case of syphilis acquired or inherited.

When the free ends of the nails are bent downward or clubbed you are to look for some obstruction to the circulation in the chest. A round, smooth, naturally symmetrical set of nails shows good nutrition. I am not quite sure but those who profess to read character by the inspection of hands include the nails in their physical explorations.

Spermatozoa.—Kolliker teaches that spermatozoa are produced in epithelial cells. If so, this caps the climax of physiological use of an epithelial cell.

The spermatozoa furnish the most lively example of protoplasmic motion in the human body. A microscope slide filled with live spermatozoa is one of the most wonderful sights on earth. The motions are so active, positive and automatic. When it is considered that one spermatozoon will impregnate an ovum—that you and I each of us came into being through such a spermatozoon—that constitution and traits of character mental, physical, intellectual, moral, are seen to be transmitted from one father to a son, or it may be from a grandfather or great-grandfather—it must be confessed that it surpasses our ability to comprehend how that so small a body as a human spermatozoon could transmit such features of distinction, so unmistakably. And then to think this comes through the medium of epithelial cells!

It seems to me that our subject furnishes material of interesting and profitable thought, and that the section of physiology offers a field which should be better cultivated than now. Far more profitable is it for us to be engaged in cultivating our mental powers, in sharpening our wits as physicians by making physiological subjects the objects of thought, rather than those of medical police and ethics.

I think it is noble and grand to realize how we live and move and have our being in our Creator, especially in the motions of ciliated epithelial cells, of spermatozoa and in the production of milk, bile, wax, sweat, fat, tears, urine, mucus, feces, and in which the epithelia play such an independent part

New York, May 30, 1892.

THE MEDICAL TREATMENT OF ACUTE TONSILLITIS AND PHARYNGITIS: A COMPARATIVE STUDY BASED ON ONE HUNDRED AND SIXTY-NINE CASES.

Read in the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY JAMES E. NEWCOMB, M.D.,

ATTENDING LARYNGOLOGIST, DEMILT DISPENSARY; ASSISTANT IN THE ROOSEVELT HOSPITAL, OUT-PATIENT (THROAT) DEPARTMENT, NEW YORK CITY.

The modern revival of therapeutics has been attended by the introduction of new remedies almost without number. It is a fair question to ask, how much have the latter benefited us? Are the new better than the old? We shall be gratified if we find that the new-comers, especially the synthetic compounds, have enabled us to cure more quickly, more safely and more agreeably than their predecessors.

It is to help answer one phase of this question that the present paper has been planned. Herewith are presented the results of treatment in one hundred and sixty-nine cases of acute tonsillitis and pharyngitis according to three distinct methods, or rather with three distinct drugs, together with some deductions which may rightly be drawn from this number of cases.

Under the title of "pharyngitis" reference is here made only to the various aspects of the catarrhal inflammations. Under "tonsillitis" are included the lacunar and parenchymatous forms of the disease, also peri-amygdalar cellulitis or quinsy. To the etiology, symptoms and possibly infectious properties of these different affections, no allusion is here made. The question is merely one of treatment.

Unfortunately, the most important factor in any therapeutic question is the most variable, viz.: the individual constitution. This renders it difficult to adopt any standard by which to judge of results attained in the employment of any remedial measure. The physician above all other men must bear witness to the truth of the old proverb that what is one man's food is another man's poison. An approximation will, however, serve us reasonably well. The most painful symptom of the maladies named is the discomfort, almost agonizing at times, in swallowing. Even here our estimate must be relative rather than absolute, for one man will be prostrated with an amount of pain which to his neighbor is a mere annoyance. The extremes may be used to balance each other. When our patients are able to swallow again with ease, the battle is in their view already fought and the victory won. It is therefore with reference to the removal of this symptom that the results hereinafter named are to be studied.

No one realizes more than the writer our tendency to generalize from insufficient data. He has therefore waited till the number of cases should become sufficiently large, and considerable confidence is felt in the results here given. Over-sanguine anticipation frequently prejudices us in favor of a new remedy. Figures must have some size, therefore, to be considered as perfectly trustworthy.

Again, the doctrine of the self-limitation of most of the acute catarrhs must be reckoned with. If the curve of our alleged "cure" coincides with that of the subsidence of the disease, the most we can say is that we have made our patients' sufferings more bearable. We have not shortened their duration. Many of the cases of the nature alluded to complete their evolution in three days. In those peri-amygdalar cases going on to suppuration we rarely find pus before the fourth day. Undoubtedly any plan of treatment may frequently (not always) prevent a mild case from assuming a more severe form.

Concerning the method by which medicines cure those affections now considered we know but little. We know that various dyscrasiæ, the rheumatic, gouty, etc., stand in a causative relation to throat troubles, and that our approved remedies for these dyscrasiæ will relieve the local pathological state. Salicylate of soda will relieve a *rheumatic* angina as quickly as a rheumatic joint. So also will guaiac and salol. But it is manifestly true that many throat cases can in no wise be regarded as dyscrasic.

The material here studied has been drawn from private practice, from my own clinic at Demilt Dispensary, and from the out-patient department of the Roosevelt Hospital in the service of Dr. Jonathan Wright, whose courtesy I would here acknowledge. It comprises, as has been said, the records of one hundred and sixty-nine cases. I have probably seen as many more during the period covered by these cases (August, 1891, to May, 1892), but many of the latter did not return for a second treatment. The number recorded have been followed till cured, and in each instance I have heard from their own lips how many hours elapsed after treatment was begun before they felt relief.

It is evident that the cases must be grouped according to the time in the period of their evolution at which they were first observed. If we begin our remedial measures on the fourth or fifth day of a simple angina, the next day or the second day after are likely to witness an improvement, because now the malady is on the decline. Accordingly it makes a great difference how early in the disease we attack the pathogenic factor. Pursuant to this view, the cases with each remedy have been divided into three groups as follows:

1. Cases in which the remedy was begun on the first or second day of the disease.
2. Cases in which the remedy was begun on the third day of the disease.
3. Cases in which the remedy was begun after the third day of the disease.

The first remedy employed was salol. The literature of this drug has become very voluminous, there being now over one hundred articles extant in different languages. To the larger number of these I have had access, but only a very few of them bear upon the present question.

It is well known that salol is decomposed by an alkali into its two component parts, salicylic and carbolic acids. Sahle[1] asserts that this decomposition can be brought about by so weak an alkali as the saliva; also by dead organic matter and bacteria. Practically we find that the remedy passes through the stomach unchanged and is split up by the pancreatic juice. This negatives the idea of any local action on the throat tissues by contact. It also suggests the advisability of flushing out the duodenum previous to the exhibition of the remedy. In the various conditions of the duodenum, Lombard[2] finds an explanation of the varying results obtained with salol. Lepine[3] has found that by diverting the pancreatic flow in animals (while salol was being given) from the bowels, the remedy was found unchanged in the stools, nor did the urine give the reaction for either of its components. On restoring the normal flow, the reaction promptly appeared. Regarding its therapy he states (Ibid.) that as compared with salicylic acid and its salts in rheumatic affections, it simply relieves the pain while the sodium salicylate attacks the disease.

Herrlich[4] used the remedy in one case of diphtheria resulting fatally. The mode of administration is not given.

Gougenheim[5] gives a warm commendation to the drug in throat disease, having employed it in twenty-two cases. His conclusions are:

1. It acts beneficially in all forms of angina, whatever the cause.
2. It quiets pain and dysphagia with the greatest rapidity.
3. In quieting pain it may shorten the duration of a quinsy.
4. It lowers the temperature.
5. In nearly all cases it diminishes the duration of the angina.
6. To accomplish the results at least 60 grains must be taken in twenty-four hours.

Seifert[6] regards it as an effective mouth wash in ulcerative processes and in diphtheria. He used a dram of a 6 per cent. alcoholic solution to a glass of warm water for a gargle.

Georgi[7] considers that it has more effect than chlorate of potash in catarrhal and lacunar anginas.

Thorner[8] was perhaps the first in this country to use the remedy for throat disease. He gave from 10 to 15 grains three times a day, and found that patients were able to swallow with ease, sometimes after only two doses. In one case beginning as parenchymatous tonsillitis, pus had already formed in the periamygdalar cellular tissue. Fifteen grains of salol (incision having been refused) enabled the patient to sleep by aborting the pain. The next day the abscess opened spontaneously. Thorner does not regard the 6 per cent. solution of Seifert as having any special advantage over other antiseptics in faucial and pharyngeal ulcerations.

Katzenbach[9] regards it almost as a specific, but gives no details concerning its administration or the nature of the cases to which he considers it applicable.

Wessinger[10] has given the remedy in 5-grain doses every two hours. In one case of pharyngitis the soreness was relieved in twenty-four hours, in another in twenty-two hours, etc. Wessinger considers salol as a heat dissipator through vaso-dilatation and consequent diminished pyrexia.

Wright[11] gives an exhaustive history of the remedy and by far the most definite account of its action in throat disease. His tabulations show that in a series of fifty cases of simple tonsillitis and pharyngitis, where treatment was begun on or before the second day (twenty-one cases) relief was experienced on an average in seventeen hours; begun on the third day, fourteen cases in twenty-seven hours. After the third day, fifteen cases in twenty-four hours. In some instances complete failure is recorded. His conclusions are in accord with those of Gougenheim. The lacunar form seemed to yield most promptly. A careful study of Wright's figures is instructive on this point, that any remedy begun early has a chance of aborting the disease. If not begun till the latter is under full headway, its opportunities of doing good are much restricted.

Kenner[12] regards it possible to cut short with salol every attack if begun early enough. We do not believe this claim to be substantiated. He has given 90 grains daily without any bad result. His dosage was 10 grains every three hours. Iron chloride tincture has also been given.

Regarding its mode of action, Waugh[13] suggests that it may rival antipyrin as an anodyne. The general impression has been, however, that its effects were entirely due to its salicylic component, 66⅔ per cent. according to Tait.[14] Here again we are confronted by the question as to whether it is more powerful than its equivalent of the acid, and as to whether this increment of power, granted that such exists, is more than could be accounted for by its association with its phenol partner. Bartholow, in his Treatise on Materia Medica, has noted that the effects of salicylic acid are increased in all directions by its association with the phenol group. These and similar considerations are all suggestive, but we have to be guided in clinical work more by results than by *a priori* views.

Lombard,[15] in a careful study of salol, says that it lowers temperature and increases the rate of breathing while there is only a slight diminution in cardiac force, but none of these more subtile effects show any relation to its behavior in throat disease.

Personally I have used salol in eighty-one cases. The dose has been 5 grains every two hours in mucilaginous suspension. Capsules have been very unsatisfactory.

The cases in which the remedy has been begun on the first or second day of the disease number thirty-six, as seen in the following table:

TABLE I.—SALOL BEGUN ON THE FIRST OR SECOND DAY.

Case.	Sex.	Age.	Previous Rheumatism.	Previous Throat Disease.	Diagnosis.	Day of Disease.	Hours Before Relief.	Remarks.

36	F	17	"	Yes	Parenchy. .	1	No relief	

Average number of hours before relief, 12.

Six cases experienced no relief. The first was a periamygdalitis in which pus was probably present. It was spontaneously evacuated later, giving speedy relief by its exit. In the second the patient, a young lady aged 28 years, was subject to bilious attacks, and said that a "bilious pill" always relieved her sore throat quicker than anything else. In the third, the angina turned out to be the forerunner of a scarlatina. In the fourth a change of treatment to iron and potassic chlorate gave speedy relief. In the fifth and sixth cases, dead failure resulted with no mitigating circumstances.

The cases in which salol was begun on the third day of the disease number fifteen, with three failures.

The cases in which salol was begun after the third day of the disease number thirty, with four failures. In one case (No. 22) of the parenchymatous form, though the pain subsided in twelve hours, the throat continued to swell for some time. A similar occurrence has been noted by both Wright and Gougenheim.

TABLE II.—SALOL BEGUN ON THE THIRD DAY.

Case.	Sex.	Age.	Previous Rheumatism.	Previous Throat Disease.	Diagnosis.	Day of Disease.	Hours before Relief.	Remarks.

15	F	22	"	"	"	3	. . . .	

Average number of hours before relief, 11.

A word or two must be said about the poisonous effects of salol. In my eighty-one cases no unpleasant effects were observed. The urine was examined in several instances and always showed a dark color suggesting carboluria. On testing it gave the reaction for salicyluric acid, the form in which the salicylic element is probably excreted. Tinnitus has been observed in a few cases but never to an uncomfortable extent. The authetic cases of salol poisoning are really very few in number. Two or three have been observed where the dosage has not exceeded sixty grains in the twenty-four hours. Church[16] gave to a typhoid patient five grains every four hours. On the third day of this dosage the patient was restless, had a herpetic eruption on the upper part of the trunk down to the level of the tenth rib. A discontinuance of the drug and the application of a carbolic ointment relieved the condition in four days.

TABLE III.—SALOL AFTER THE THIRD DAY.

Case.	Sex.	Age.	Previous Rheumatism.	Previous Throat Disease.	Diagnosis.	Day of Disease.	Hours before Relief.	Remarks.

Average number of hours before relief, 18.
Average of all the salol cases, 14⅓.

Demme has observed urticaria in one case after a clyster of two grammes, but in a somewhat extensive use of this quantity daily by the mouth had no other case of poisoning. It is without the province of this paper to go into details of salol poisoning. Suffice it to say that in a mild degree gastro-intestinal irritation is the leading feature. In more profound cases there are evidences of renal disturbance. All agree that the carbolic factor is the real damaging agent. Fatal results are not unknown. Derignac[17], Aufrecht,[18] Hesulbach,[19] Cartaz,[20] Morel-Lavalle,[21] Josefowitsch and Chlapowski have all made contributions to the literature of the drug's toxicology. One writer goes so far as to say that he regards it imprudent to give salol without at the same time giving its antidote sulphate of soda.

---

[15] Bull. gen. de Therapie, Paris, No. 16, 1887.

[16] N. Y. Med. Record, March 3, 1880.

We need not be at all disturbed by the slight coloring of the urine which will result from the daily dosage of sixty grains.

The second remedy employed was guaiac. It was first suggested for tonsillitis by Sir Thomas Watson. Its reputation for the relief of rheumatic manifestations is as old as guaiac itself. Hence came its early employment in all throat conditions regarded as the expression of the rheumatic diathesis. Edes,[22] credits it with the power to absort peritonsillar inflammations but regards it as without any specific action the lacunarform.

TARLE IV.—GUAIAC BEGUN ON THE FIRST OR SECOND DAY.

Case.	Sex.	Age.	Previous Rheumatism.	Previous Throat Disease.	Diagnosis.	Day of Disease.	Hours before Relief.

10	M	21	"	No	"	3	36	

Average number of hours before relief, 23½.

In one case the remedy caused an acute exfoliative dermatitis. In two cases failure is reported and both went on to periamygdalitis.

The second group comprises ten cases.

Here also two failures are recorded, in one of which the patient grew distinctly worse in spite of the remedy.

The third group (treatment begun after the third day) embraces fourteen cases.

TABLE VI.—GUAIAC BEGUN AFTER THE THIRD DAY.

Case.	Sex.	Age.	Previous Rheumatism.	Previous Throat Disease.	Diagnosis.	Day of Disease.	Hours before Relief.	Remarks.
1	F	26	No	Yes	Parenchy.	4	12

13	M	32	Yes	No	"	28	24	
14	F	11	"	"	"	4	8	

Average number of hours before relief, 11.
Average of all the guaiac cases, 17⅓.

Failure is here recorded in four cases. In one case pus was present but reformed after incision. One case of the parenchymatous form ran on to the peritonsillar but was finally relieved in sixty-six hours without suppuration.

Certain disadvantages of guaiac claim a brief attention. It is an extremely disagreeable remedy to take. Sajous' method of using a menstruum of hot milk does but little to lessen this unpleasant feature. S. Solis Cohen[23] highly extols the compound guaiac gargle made as follows:

Take ʒij of chlorate of potash, dissolve in hot water and set aside. Then take a ℥vj bottle, put in it ʒvj of clarified honey, and smear the sides of the bottle with it, shaking it well. After this add, teaspoonful by teaspoonful, shaking well after each additional spoonful, compound tincture of chinchona fʒij, and ammoniated tincture of guaiacum fʒij. To this solution add gradually the chlorate of potash which has been set aside, shaking the mixture thoroughly, and to this add water q. s ad ℥vj. Every half hour, or hour, or two hours, the patient should gargle or bathe the throat with a teaspoonful of this solution. Every two hours let him swallow a half teaspoonful or a teaspoonful.

Cohen found that if begun early it would relieve most cases in a few hours.

Potsdamer[24] corroborates these results obtaining in one case of a series of nine, relief in six hours, and in all by the third day.

The third remedy employed was salicylate of soda in five grain doses in solutions every two hours.

Several of the sodium salts have long enjoyed a good reputation for alleviating throat troubles. Many continental authors recommend the simple bicarbonate locally applied. Boisliniere[25] treated seventy-five cases with sodium benzoate and found that pain was relieved in from twelve to thirty-six hours, truly a remarkable showing. Favorable reference to the salicylate is frequently found. Hunt[26] found his cases relieved on an average in twenty-four hours. Mackay[27] and Hormadge,[28] also commend its use. In fifty-seven cases treated by the latter none were even threatened with suppuration. The pain was nearly gone the next day and swallowing was easy.

14	M	22	No	No	Parenchy. .	2	4	
15	M	16	"	"	Peritons. . .	1	8	Incision; no pus.

Average number of hours before relief, 24.

Here again two complete failures are chronicled. In one, a hot bicarbonate gargle afforded relief in twelve hours. The second grew steadily worse for two days, and was then lost sight of.

The second group embraces twelve cases.

TABLE VIII.—SODIUM SALICYLATE BEGUN ON THE THIRD DAY OF THE DISEASE.

Case.	Sex.	Age.	Previous Rheumatism.	Previous Throat Disease.	Diagnosis.	Day of Disease.	Hours before Relief.	Remarks.
1	F	26	Yes	No	Acute phar. .	3	20	
2	F	31	No	Yes	Parenchy. .	3	18	
3	F	57	"	No	Peritons. . .	3	No relief	Incision 2 days later; pus.
4	F	30	fam.	"	Lacunar . .	3	24	
5	F	20	. . .	Yes	parenchy. .	3	20	
6	F	8	No	. . .	" . .	3	4	
7	M	39	"	Yes	" . .	3	36	
8	M	22	"	"	Peritons. . .	3	24	Incision; no pus.
9	M	24	"	No	" . .	3	12	
10	F	31	"	"	. . . .	3	No relief	Iron and potash relieved in 12 hours.
11	F	36	"	"	Parenchy. .	3	36	Also acute pharyngitis.
12	F	37	"	Yes	Peritons. . .	3	8	Incision; pus.

Average number of hours before relief, 17.

Of the two failures, pus formed in one after two days. A second obtained speedy relief from the iron and potash gargle.

The third group comprises seventeen cases.

Six failures are here recorded. One was quickly relieved by a hot bicarbonate of soda gargle, and a second by iron and potash internally. In the other cases of failure nothing of special interest is recorded.

To summarize, then: Out of 169 cases 81, or 48 per cent. treated by salol, experienced relief on the average in $14\frac{1}{3}$ hours; 44, or 26 per cent. treated by guaiac, in $17\frac{1}{3}$ hours; 44, or 26 per cent. treated by sodium salicylate, in $18\frac{1}{2}$ hours. The preference, therefore, is in favor of salol.

One therapeutic suggestion mentioned by Routh[29] is worthy of note. He believes that if salicin (with which he has treated many cases), is continued for a week or so after the subsidence of the acute symptoms, it will prevent the chronic hypertrophy of the tonsils which we so often observe as a sequel of repeated attacks.

It is pertinent here to consider what bearing this mass of clinical material has on what we may call the rheumatic aspect of sore throat. No small number of authorities regard throat troubles of the nature described as always a manifestation of the rheumatic diathesis. This is an extreme view and one not, I think, upheld by facts. It is manifestly a begging of the question to assert that this is always so in the case of first attacks. In my own cases, this point has been carefully inquired into, and a definite answer obtained in all but seven. Dividing then the remaining 162 cases into rheumatic and non-rheumatic groups, we find forty-seven, or 29 per cent., in the former, and 115, or 71 per cent., in the latter. In the former are included all in which there has been either a personal rheumatic attack, a family history of rheumatism, growing pains, or any other of the composite features of the disease. These figures differ somewhat from those of Haig Brown,[30] who found that out of 119 cases, twenty-eight had rheumatic pains, thirty-eight rheumatism, and ten had had rheumatic parents—that is, seventy-six, or 64 per cent., had some rheumatic tendency. Fowler[31] believes that it will be found that 80 per cent. of all cases of rheumatism have had previous sore throats.

TABLE IX.—SODIUM SALICYLATE BEGAN AFTER THE THIRD DAY.

Case.	Sex.	Age.	Previous Rheumatism.	Previous Throat Disease.	Diagnosis.	Day of Disease.	Hours before Relief.	Remarks.
1	F	21	No	Yes	Peritons. . .	11	12	Incision; no pus.
2	F	23	"	"	Acute phar. .	4	Failure	Soda gargle relieved.
3	M	29	fam.	"	" . .	5	12	
4	F	39	"	"	Peritons. . .	. .	No relief	
5	F	22	"	"	Sub-ac. phar.	4	21	
6	F	21	No	"	Acute phar. .	7	12	
7	M	20	fam.	No	" . .	7	36	
8	M	20	No	"	" . .	7	No relief	
9	M	32	. . .	Yes	Parenchy. .	8	48	
10	F	30	fam.	"	Lacunar . .	4	No relief	
11	M	26	No	"	Peritons. . .	4	48	Incision; no pus.
12	M	25	fam.	"	Parenchy. .	4	21	
13	F	15	Yes	"	Peritons. . .	5	12	
14	M	21	No	"	" . .	8	21	
15	F	28	"	"	Acute phar. .	10	8	Acute lingual tonsillitis.
16	F	10	"	No	Parenchy. .	5	None	Iron and potash relieved.
17	M	28	. . .	Yes	Peritons. . .	4	"	Incision; no pus.

Average number of hours before relief, 15.
Average in all sodium salicylate cases, $18\frac{1}{2}$.

I cannot help believing that in many of these cases, a previous rheumatic history is merely a coincidence. This view receives a certain confirmation in the therapeutic results reached in the rheumatic and non-rheumatic cases respectively. Thus in the forty-seven cases of the former group relief averaged sixteen and one-half hours, while in the 115 cases of the latter group, the average was a trifle over seventeen hours—practically the same.

My views, therefore, in regard to the treatment of acute simple sore throat of the varieties alluded to, may be summarized as follows:

1. I believe that in salol we have a remedy which, in the vast majority of cases, will give relief quicker than any other. Occasionally it utterly fails. Where it does so, I have found that iron tincture with potassic chlorate seems to be the best substitute. It is my conviction that this latter combination finds its best field in those patients who have already had many previous attacks, and in which there is more or less of an interstitial deposit of connective tissue in the mucous membrane. Salol is to most patients

far more agreeable than sodium salicylate, and vastly more so than the nauseating guaiac.

2. If peri-amygdalar infiltration has already set in, it is an open question in every case as to whether we shall be able to prevent suppuration. An incision is I believe indicated wherever there is engorgement, even though, no pus has yet formed. The latter rarely comes before the fourth day. If it is not found no especial discomfort, then or thereafter, results to the patient from the incision, particularly if a little cocaine is used. The incision should be made where the pus is most likely to form, viz.: high up, in front of and above the pillars, far more commonly the anterior.

3. If pus is present, free incision towards the median line is indicated. It should be followed by a hot bicarbonate of soda gargle, together with poultices on the outside.

4. Care should be taken to thoroughly open the bowels with a mercurial and a saline at the commencement of treatment in any case.

PURULENT BRAIN DEPOSITS, AND PHLEBITIS AND THROMBOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

BY FRANK ALLPORT, M.D.,
OF MINNEAPOLIS, MINN.,
PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLOGY IN THE UNIVERSITY OF MINNESOTA, ETC.

(*Continued from page 645.*)

It has been interesting to note the relative frequency of males and females to these diseases, and my statistics show the following:

Males	86 cases.
Females	46 "
Sex not stated	37 "
	169 cases.

The extra liability of males to diseases of this character is probably due to the increased exposures incident to male life.

More cases occurred at the ages of twenty-three and twenty-five, and the average age appears to be between nineteen and twenty.

The ages most frequently involved are from seventeen to twenty-six inclusive, which is perhaps due to youthful indiscretions and the increased exposures common to this period.

These statistics show a proneness to such diseases during the first three years of life, which is probably due to the thin character of the cranial bones, the tendency to middle ear abscesses during childhood, and the inability to give to babes suffering from aural complaints the care possible in later life.

As to which ear is most frequently involved, the statistics show as follows:

Right ear	81 cases.
Left ear	69 "
Ear not stated	19 "
	169 cases.

Why the right ear is more frequently affected is not an important question, as the additional frequency of involvement is small, only twelve more cases being attributed to the right than to the left ear, and the absence of notes upon this point renders conclusions doubtful.

Let us first consider, in as concise a form as possible, the subject of the intra-cranial presence of pus, outside of the veins and sinuses, dependent upon an ear disease. This includes, of course, not only brain abscesses, but deposits of pus, in any situation coming under this heading, either in patches, or diffused generally over certain places or spaces.

The importance of this subject may be inferred from Barr's observations, that the deaths in London for one year from brain abscesses, following otorrhœa, were eighty-six; and in the eight principal towns of Scotland were twenty-six.

Barker considers 50 per cent. of all cases of brain abscess to be due to otorrhœa, and his view is shared by von Bergmann. Lebert places the proportion at 25 per cent., while Meyer and Ogle believe it to be about 30.

The starting point and focus of this trouble is the middle ear. It may result from either acute or chronic otorrhœa, with the tendency largely in favor of the latter.

This observation applies to all fatal cerebro-aural affections, and the statistics that I have framed upon this subject are as follows:

Cerebro-aural affections dependent upon chronic otorrhœa	118 cases.
Cerebro-aural affections dependent upon acute otorrhœa	10 "
Not stated	41 "
	169 cases.

A fair proportion of these ten cases proceeding from acute otorrhœa were instances of brain abscesss. This is especially noteworthy, because many observers discredit the fact that brain abscesses are *ever* produced from acute otorrhœa, and von Bergmann is especially wedded to this belief. My records show six cases of this character, and the reporters are Bürkner, De Rossi, Knapp, Pooley and Allport. These were strictly cases of brain abscess, starting from acute purulent otorrhœa.

Acute tympanic abscesses have a natural tendency to recovery, even if left entirely to themselves, and favorable results frequently follow even the most disadvantageous circumstances — hence the infrequency of cerebro-aural complications. Chronic otorrhœa, on the contrary, is a much more dangerous condition, and when the proximity of the middle ear, mastoid antrum and cells to the brain and its membranes, and the different sinuses, veins, etc., is considered, it is not singular that such should be the case. It is in chronic otorrhœa that we observe the foul and irritating discharge, either free or retained; also granulations and polypi, necrosis of the ossicles, tympanum, mastoid antrum and cells. Here we find necrotic openings in the walls of these cavities, and encroachment of the disease to the intra-cranial cavity. And here we notice the carrying of the disease to the brain and sinuses by the more insidious process of germ migration, by means of the minute osseous foraminæ or small blood-vessels that are not infrequently noticed connecting the tympanum, antrum, or cells, with the intra-cranial cavity. Cerebro-aural affections are especially liable to occur when a tympanic discharge has been suddenly stopped, and there can be no doubt that the antiseptic powders now so freely used by insufflation, have precipitated many attacks of this nature. Such powders undoubtedly have their use, but they should be handled with judgment, and should *never* be used in acute otorrhœa, and when employed, the parts should simply be lightly dusted, and not heavily coated.

How does the disease extend from the tympanum, antrum and cells, to the intra-cranial cavity?

Probably the most frequent method of extension is through the roof of the tympanum into the middle cerebral fossa, and from thence to the temporal lobe. In looking over the list of necrotic openings in the temporal bone, as shown by the autopsies in my collection of cases, I find that by far the most frequent location for a necrotic fistula is in this situation. The next most frequent location for such an opening, is through the inner mastoid plate to the posterior cerebral fossa, and from thence to the cerebellum.

These circumstances are quite significant in localizing brain abscesses following otorrhœa, as, if mastoid disease can be eliminated from the case, either by operation or otherwise, the probability is that the abscess is in the temporal lobe.

The disease may extend by necrosis also, through the internal ear, especially by way of the semicircular canals. And it may be directly carried to the brain, even when no necrosis is present, by several methods, as described by Barr.

1. By the foramenæ in the bone, through which pass vessels, nerves, and connective tissue.

2. By the destruction of the two fenestral membranes; in which case the internal ear becomes invaded, after which the only intervening tissue is the perforated lamella of bone, through which pass the fibres of the auditory nerve.

3. Part of the blood supply to the tympanic cavity comes from within the cranium, and the accompanying veins might carry disease to the brain, either by germ migration, or phlebitis.

Inflammation probably passes from the dura to the brain by contiguity of tissue, as there is no direct vascular or lymphatic connection between the two. Usually the abscess is located in the immediate vicinity of the focal point of disease, although this is not always the case, as it sometimes happens that healthy dura mater and even brain tissue, may intervene between the seat of original disease and the abscess. Under these circumstances infectious micro-organisms probably pass into the circulatory system from the purulent points, or are transported along the connective tissue which envelops the vessels.

The subject of diffused purulent deposits within the cranium, and that of localized abscesses, may be considered practically under one head. Isolated, encapsulated brain abscesses, following aural disease, are not of very frequent occurrence, and when found, have not been demonstrated to possess distinctive diagnostic features that would necessitate separate consideration. Indeed, my statistics only show a record of nine encapsulated abscesses in all the cases.

Almost all cerebro-aural pus deposits are accompanied by more or less meningitis, either simple or purulent. It is usually localized at the focus of disease, and in consequence its most common seat is near the tympanic roof, although it may be much diffused, and even extend down to the membranes of the cord.

Meningitis and other brain diseases do not always follow destruction of the osseous walls of the skull. The dura mater is extremely tough and fibrous in its structure, and often resists for a long period the destructive action of pus, before softening and perforation occur. Indeed, some cases have been found where the tegmen-tympani was congenitally absent, and yet no brain lesions have followed a chronic purulent otorrhœa. Perforation of the dura mater, however, is not at all necessay to the extension of the disease to the brain membranes and brain substance itself.

When purulent meningitis takes place, it more frequently affects the meninges at the base of the brain, than those at the convexity. This is probably due to the downward tendency of inflammation. The substance of the cortex of the brain usually becomes more or less infiltrated with pus in these cases.

Besides being found in the membranes, pus may be found in almost any part of the brain substance, and is often generally distributed over an entire hemisphere, and sometimes is deposited on the opposite side of the brain from the point of lesion.

Abscesses may be situated in different parts of the brain, and are most frequently found in the temporal lobe and the cerebellum, in the order of their mention. My records show the presence of abscess in the temporal lobe forty times, and in the cerebellum thirty-one, and they are not infrequently found in the middle lobe.

It must be remembered, that while I have recorded 169 cases of intra-cranial diseases following otorrhœa, only ninety-eight of them were recorded as abscesses proper. This magnifies the percentage of abscesses found in the temporal lobe and cerebellum.

Notwithstanding the fact that many brain abscesses are connected with the tympanum, by a fistulous opening through the tegmen-tympani, it is a noteworthy fact, that the *body* of the abscess is not usually located *immediately* above the diseased tympanum. In the event of its being here situated, the roof of the tympanum would be a strong vantage ground for operation, and many abscesses would probably be self-limited, and quiescent in their nature, owing to a spontaneous and natural drainage through the tegmen.

McBride thinks that if the auditory nerve is involved, as shown by the lack of bone conduction, the abscess will probably be found behind the tentorium. Barker concludes that cerebellar abscesses are *always* found at the outer and anterior portion of the cerebellum, near the petrous. This view cannot be substantiated, for, while it is true, this is by far the most frequent point of lesion, cerebellar abscesses are sometimes found in other parts of the cerebellum, as will be noticed by a perusal of some of the reports of autopsies in my statistics.

Korner considers that children under ten years of age, seldom suffer from cerebellar abscesses, on account of the great distance of the posterior fossa of the skull from the auditory meatus at this age.

Hulke believes that in young people, the abscess is located, usually above the tentorium cerebelli; in older people, below it.

Abscesses are sometimes multiple, connected or unconnected, and this should always be borne in mind, in operative interference, if a thorough opening of an abscess does not lead to recovery.

(To be continued.)

SPONDYLITIS.

BY JOHN RIDLON, A.M., M.D.,
OF CHICAGO, LATE ASSISTANT SURGEON TO THE VANDERBILT CLINIC, NEW YORK; SECRETARY OF THE AMERICAN ORTHOPEDIC ASSOCIATION, LECTURER ON ORTHOPEDIC SURGERY IN THE NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, PROFESSOR OF ORTHOPEDIC SURGERY IN THE POST GRADUATE MEDICAL SCHOOL, CHICAGO,
AND ROBERT JONES, F.R.C.S.E.,
OF LIVERPOOL, ENGLAND, HONORARY SURGEON TO THE ROYAL SOUTHERN HOSPITAL, LIVEPOOL, CORRESPONDING MEMBER OF THE AMERICAN ORTHOPEDIC ASSOCIATION.

[Copyrighted by John Ridlon, M D]

Spondylitis, also called Pott's disease, spinal caries, etc.. may be the result of traumatism, syphilis, or tuberculosis; or it may follow scarlet fever, measles, whooping cough, etc., and appear to be dependent upon the morbific germ of those diseases; but however it begins, or whatever be the specific germ assumed to be the cause, the symptoms presenting and the indications for treatment are the same, and all cases sooner or later show evidences of the presence of the tubercular bacillus. It is probable that the disease may commence in any of the connective tissues composing the spinal column, but there is little satisfactory evidence to show that it ever begins elsewhere than in the cancellous tissue of the vertebral bodies, or upon their anterior aspects. Very rarely has the disease been found so located as to render it a fair assumption that the primary focus was located either in the intervertebral discs, the laminæ, arches, articular facets, or processes.

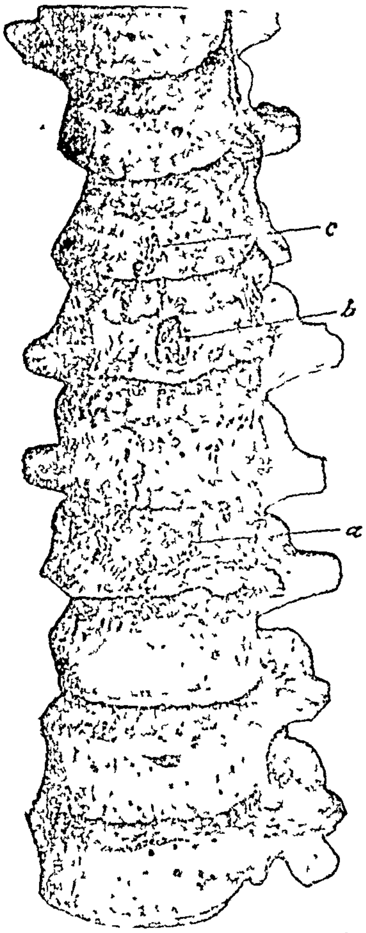

FIG 1 —Lumbar and dorsal spondylitis commencing. *a* Opening in anterior surface of second lumbar vertebra *b* Similar opening in the twelfth dorsal vertebra *c* Beginning erosion of the eleventh dorsal vertebra

In traumatic cases the early symptoms vary with the injury received; the late symptoms are those of the ordinary tubercular case. Spondylitis arising without assignable cause in very young children, cases of multiple joint disease where spondylitis is present at two points separated by one or more healthy vertebræ, or coexisting with disease at some other joint, and spondylitis in classes notoriously syphilitic, may be suspected of having a syphilitic rather than a tubercular origin and worthy of the administration of large doses of mercury and iodide of potash. It is only in the improvement which follows this treatment that these cases materially differ from the ordinary tubercular cases. Those cases which follow scarlet fever, measles, etc., show no peculiarities except a proneness to early suppuration. The ordinary tubercular case presents the irritative symptoms indicative of inflammation in the vertebral bodies. These will be discussed in detail at another time.

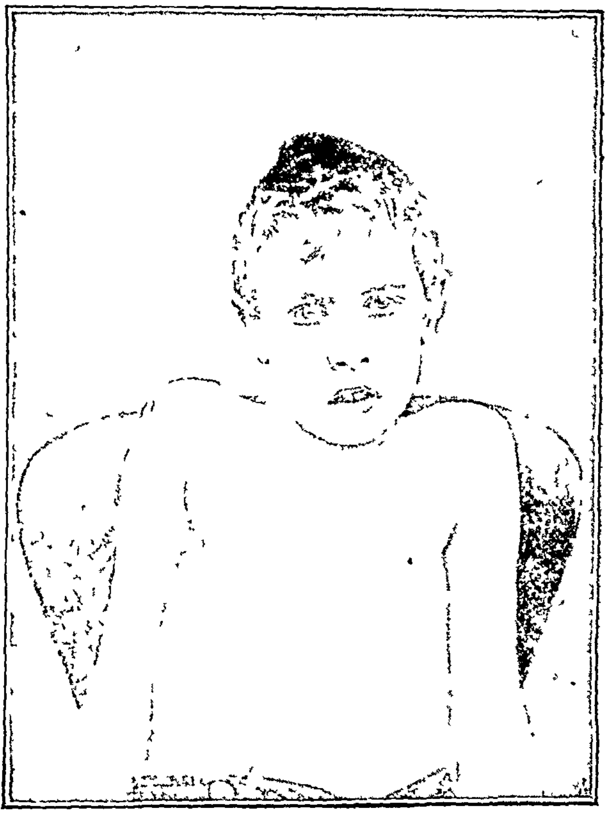

FIG 2 —Pained facial expression in spondylitis

The principles of treatment are immobilization and relief from weight bearing; in a word, *physiological rest of the diseased part*. The means which the surgeon employs to secure this physiological rest will be discussed in a later paper.

Symptoms in general.—Certain symptoms are common to the disease in whatever part of the spine it may be located; certain other symptoms are peculiar to the part of the spine affected. The symptoms common to the disease in any part of the spine are as follows: The face expresses apprehension, pain and premature old age. The patient walks and moves with care as if to avoid any jar or sudden movement. There can be obtained a history of uneasiness, fretting, and irritability, and for some time the patient has been disinclined to his usual active exercises and has been easily fatigued. Distant pain, felt in the terminal filaments of the nerves whose motor branches go to supply the muscles controlling motion of the spine at the point of disease has generally been felt, though it may have been absent, a may also have been restlessness, crying, and screaming during the first hours of sleep. Deformity may or may not have been noticed; and the complications—abscess and paralysis—may or may not have appeared.

For the proper examination of a patient he should be stripped naked. Girls who have reached the age of puberty and women should receive certain consideration, and it is the custom to examine such with the back alone bared. It is convenient to have the undershirt put on in front as an apron, with the sleeves pinned or tied about the neck; the skirts can then be dropped to a level with the greater trochanters and held with a large safety pin, or by a piece of bandage tied around the hips. The back is then inspected for any lateral deviation, excurvation, incurvation, or prominent vertebræ. If found, the disease may be suspected of being present at the middle of the curvature; but it must be remembered that spondylitis, easily demonstrable is, usually present some months before deformity of the spinal column is apparent. All of the normal motions should now be tested, both actively and passively; the head should be rotated to right and to left, and the shoulders twisted in the same directions while the pelvis is held steady; the spine should be bent forward and backward, and to right and to left. Any portion which shows rigidity to *all* the normal motions is, or has been, the seat of an inflammatory process; but if there be rigidity to bending in one direction only, or if bending in any one direction be normally free, the diagnosis of spondylitis is rendered extremely doubtful. It is upon this rigidity, which for a long time is due solely to involuntary muscular spasm, that the diagnosis must depend; it is ever present, both sleeping and waking, and nothing abolishes it except profound anæsthesia and the termination of the inflammatory process. It is the first symptom to appear and the last to disappear; and when, and only when, it is no longer present can a cure be safely predicated.

Tenderness to direct pressure over the suspected area, unless local abscess be present, will not be found. This local tender point, which is taught by the professors of and the text-books on general surgery as *the* diagnostic symptom, always counts against rather than in favor of a diagnosis of spondylitis. It should be remembered that the disease is located in the vertebral bodies, and usually in their anterior parts, and in any case is far beyond the reach of direct pressure, and consequently tenderness to direct pressure is, unless supported by strong confirmatory evidence, to be looked upon as indicative of some other condition than the disease in question.

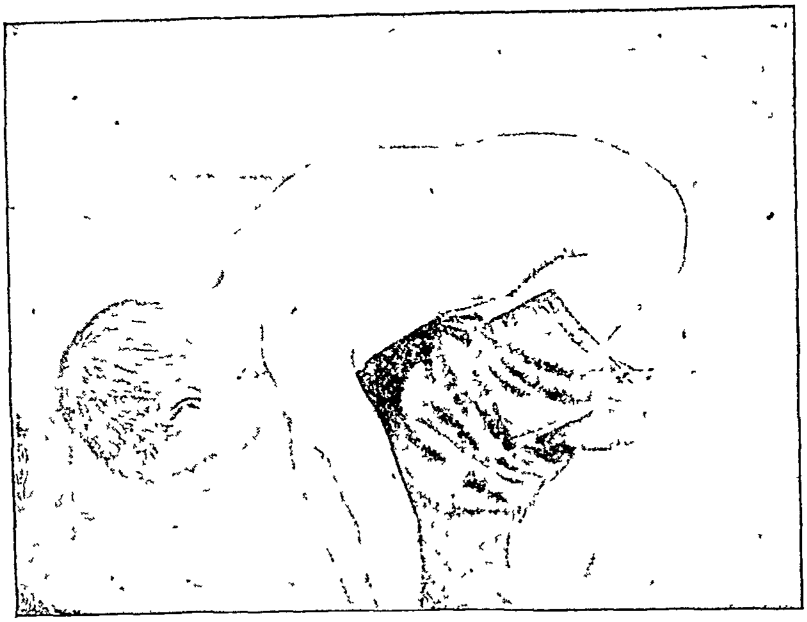

FIG 3—Lumbar spondylitis Stooping with rigid lumbar spine.

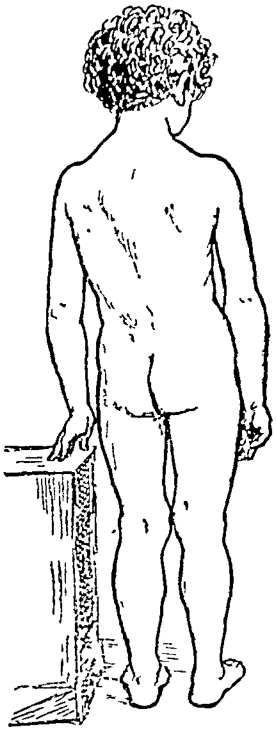

FIG 1—Lateral deviation in the spine in commencing spondylitis.

Downward pressure and concussion on the head, and sudden twisting of the spine by wrenching at the shoulders when the patient is off his guard, are tests as unnecessary as harmful. They will not be found to be of any value in the very early period and can scarcely fail to inflict injury as well as pain upon the patient when the disease is at all advanced. Sooner or later deformity of the spine appears, and a lateral curvature with or without twisting of the vertebræ—rotation—often appears before kyphosis, the so-called "angular curvature," makes its appearance. If but one, two, or three vertebræ be affected, and if the destructive process has been considerable, the deformity fairly approximates an angle; but if several vertebræ are diseased each to only a slight degree, the deformity will be a curve.

Motor paraplegia affecting both lower extremities and at times the bladder and rectum, and at times also the upper extremities, may come on before the bony deformity or with the deformity, or comparatively late in the disease. It is generally due to thickening of the membranes of the cord from the contiguity of the inflammation in the bone, or to an actual infiltration with tubercular material. Paraplegia occurs by far the most frequently when the disease is located in the upper dorsal region. It bears no relation to the acuteness of the angle; it may disappear while the bony deformity goes on increasing; and it has seldom been shown to depend upon bony pressure. The paraplegia is characterized by an exaggeration of all the tendon reflexes in the affected extremities, a tonic spasm of all the muscles, and an inability, more or less complete, to move any portion of the affected parts.

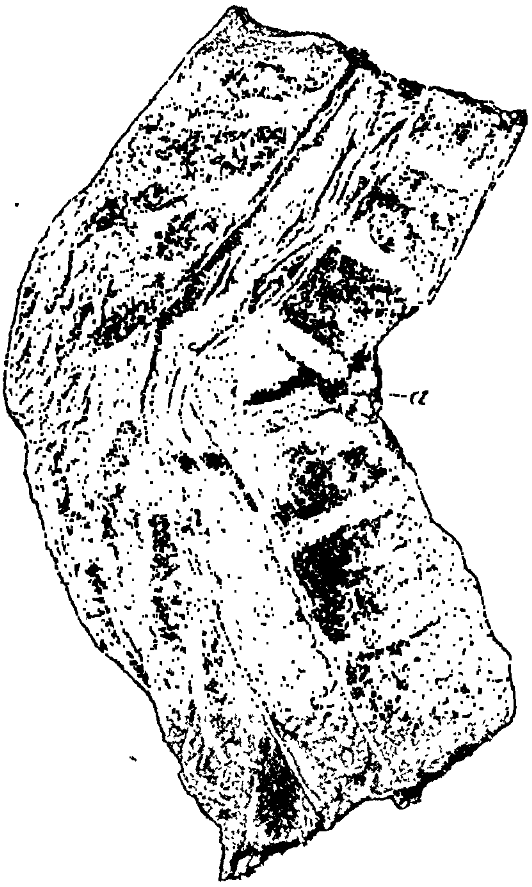

FIG. 5.—Lower dorsal spondylitis, with ordinary deformity. Almost complete absence of the body of the ninth dorsal vertebra. In front is a fistulous canal leading to a psoas abscess.

Although tubercular "pus" is probably formed to some extent, the tubercular abscess does not appear in all cases. Abscesses are quite frequently seen when the disease is in that part of the spine below the diaphragm; less frequently with disease in the cervical region, and still less frequently with disease of the dorsal spine above the diaphragm. The abscess may make its way in any direction, opening externally, or into any of the open or closed cavities of the body, or it may become absorbed even after it has attained very considerable proportions.

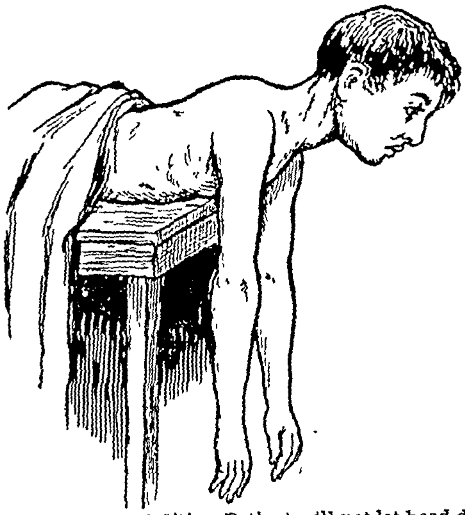

FIG. 6.—Cervical spondylitis. Patient will not let head dangle.

Cervical spondylitis is most frequently found in the upper two or three vertebræ. When the cervical spine is suspected, before deformity has occurred, in very young children, the child should be examined by placing *him prone across* the parent's knees. If disease exists the child will not let the head dangle no matter how prolonged the examination may be. If placed supine, he will show no inclination to bend the head toward the sternum as in the first act of rising. As the disease advances malposition comes on. If the upper portion of the cervical spine be affected, twisting of the head may be expected; with disease somewhat lower down the head is advanced, the chin dropped on the chest, an angular projection of the spine at the diseased point may be felt, and the posterior spinal muscles stand rigidly out and may simulate an abscess in appearance. When the disease is still lower down the chin is elevated and relatively somewhat advanced, and the head is thrown back towards the shoulders, and in extreme cases may rest upon them. The face expresses apprehension, and the head is moved, if the patient can move it at all, with anxious care. All motions both active and passive at the point of disease are restricted to a greater or less degree, or

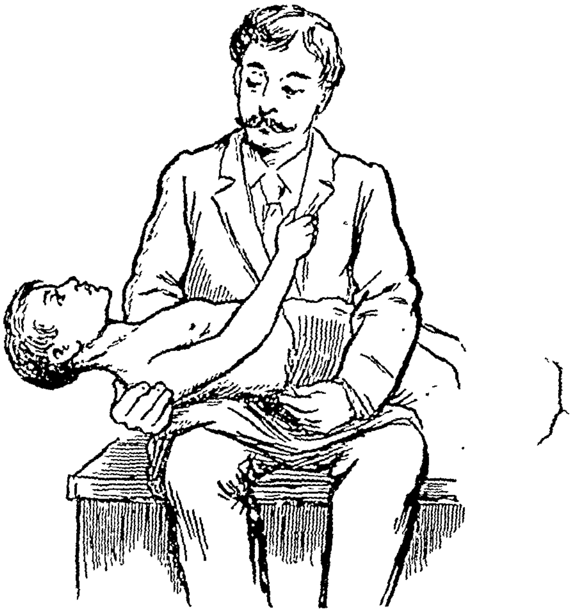

FIG. 7.—Cervical spondylitis. Patient will not let the head dangle.

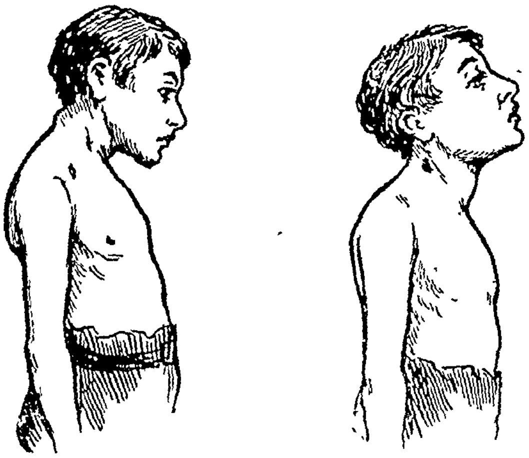

FIG. 8.—Cervical spondylitis. Chin dropped.

Cervical spondylitis. Head [illegible]vanced and chin raised.

wholly abolished. Pain may be complained of running up the back of the neck and head, down the arms or in the chest. Abscess does not frequently occur; when it does it usually points laterally on one or the other side of the neck; it may point in the pharynx. The pharynx, however, need not be examined unless some symptom point to abscess in iat location. Before the formation of abscess the nger in the throat reveals nothing, it is very repul-ve to the patient, and the normal prominence of ie vertebral bodies may mislead the surgeon. Paraplegia is seldom a complication of spondylitis in the cervical region. Occurring, it may affect the lower extremities alone, as is the rule, or the upper extremities as well. Striking downward upon the top of the head with the open palm to test the sensitiveness of the veterbræ is a useless and a most barbarous procedure.

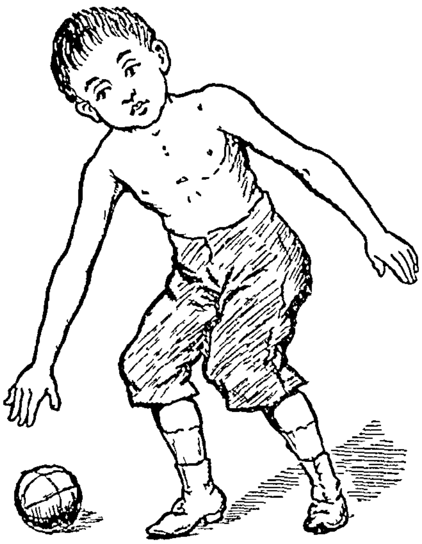

FIG 10—Dorso lumbar spondylitis. Carefully reaching for an object on the floor

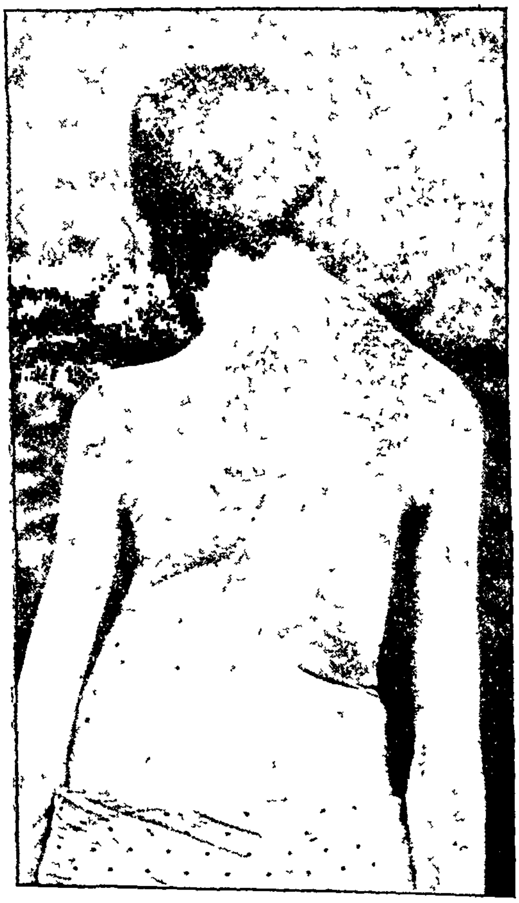

FIG 11—Cervico dorsal spondylitis Lateral deviation with marked tation

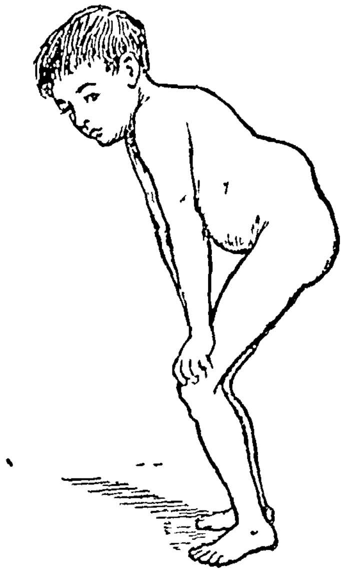

FIG 12—Lumbar spondylitis Patient climbing up his own legs.

Dorsal spondylitis is much more frequent than disease in the cervical and lumbar regions. Before the appearance of kyphosis the diagnosis must depend upon the persistent distant pain, a disinclination to indulge in rough play, a growing tendency to stand with the elbows resting upon a chair or table, a grunting respiration, and an inability to rise from a stooping posture or pick up an object from the floor without resting the hand upon the knee; and it should be borne in mind that patients are frequently treated for many months for bellyache before deformity appears. Any distant pain which does not yield readily to the proper medication should lead to a careful examination of the spine. Often there is crying when the child is lifted, and cough accompanying the grunting respiration.

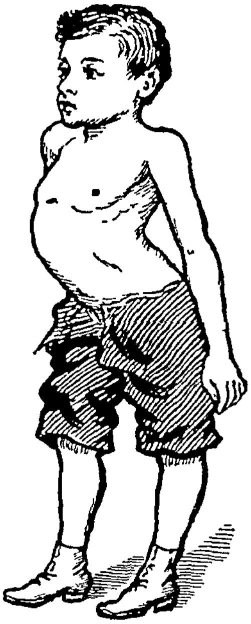

FIG. 13.—Dorsal spondylitis. Prominent chest.

If the upper two or three dorsal vertebræ be the ones involved, the head may be thrown backward and the neck held rigid to forward and lateral bending; and paraplegia may even come on before any kyphosis can be made out. When disease is located in the lower dorsal region, the patient may limp and complain of pain in the thigh, simulating hip disease, before any deformity is noted. Lateral deviation of the column, with or without rotation of the vertebræ, is often present before the antero-posterior deformity appears. In very young children, before any spinal deformity has appeared it is convenient to examine them by placing them across the separated knees of the parent. If there is disease the spine will not sag into an anterior curve in the normal way. If placed sitting upon a table with the knees straight, the child will not bend forward, arching the spine in the usual way. The patient is disinclined to forward bending, squatting with rigid spine instead of stooping when picking up an object from the floor, and evinces weakness on rising, often regaining the erect posture only by climbing hand over hand up his own legs.

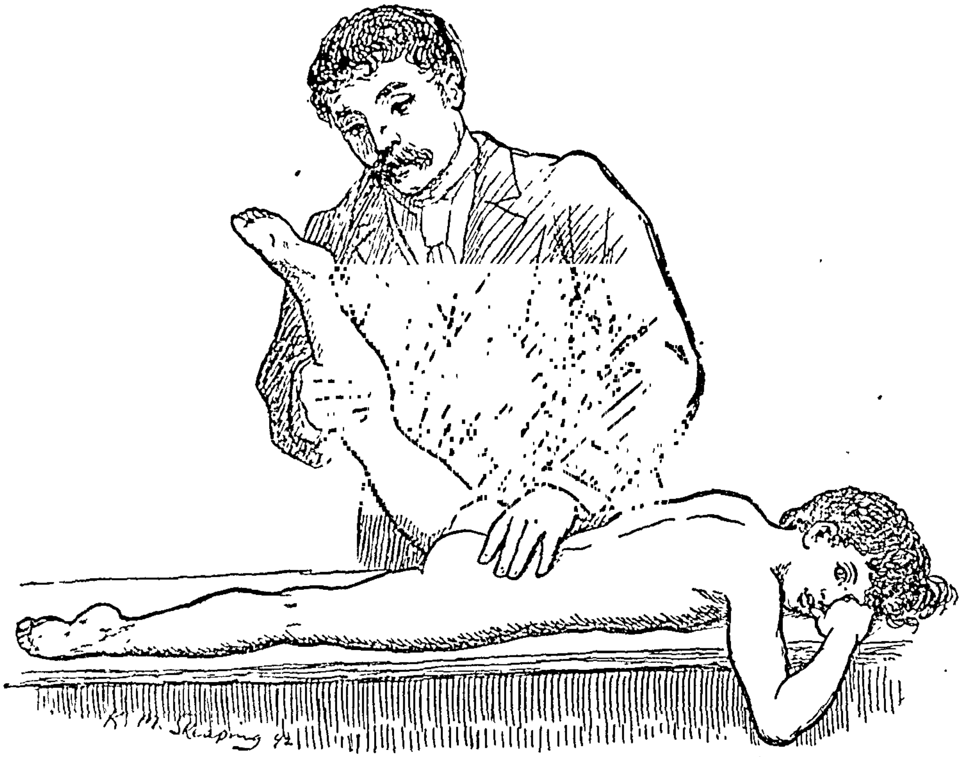

FIG. 14.—Testing for psoas contraction. Shows normal extension.

There seems to be an almost universal belief among the rank and file of the profession, and this belief has been fostered by nearly all of the teachers and writers on general surgery, that the most early and constant, and in fact *the* diagnostic symptom of spondylitis is *tenderness on pressure over the point of disease.* There is no lack of knowledge as to the pathological anatomy; it is perfectly well known that the lesion is located in the vertebral bodies, and usually in their anterior portions, and that it is quite impossible that there should be tenderness on pressure over the spinous or the transverse processes. Unless then there be disease of the processes or laminæ, an exceedingly rare condition, or unless an abscess which will be readily detected by palpation be present, *tenderness on pressure will not be found in spondylitis.* In a doubtful case its presence must count as an important symptom *against* spondylitis.

When kyphosis has appeared however, the diagnosis will be readily made, for in addition to the peculiar and striking deformity, all of the symptoms heretofore mentioned are likely to be found on careful investigation. Sooner or later projection forward of the chest takes place, compensatory and proportionate to the angular deformity at the back. Paraplegia, which is more common when disease is located in the upper dorsal spine than elsewhere, may come on early before any deformity has appeared, or at any time during the course of the affection, or very late in the disease, and may recur again and again. It begins with exaggeration of the tendon reflexes, stumbling in walking, increasing lack of muscular control, and goes on until all control over the lower extremities is lost, and the limbs are held rigidly extended; at times they draw up with spasmodic crampings and may suddenly, without the patient's volition, be extended with a jerk. Passive flexion at the ankles induces marked ankle-clonus. Rarely the sensory nerves and at the same time the bladder and rectum are affected.

Abscess does not frequently appear when the disease is above the diaphragm, although it is probable that tubercular pus forms to some extent in all cases; when the abscess does present it usually makes its appearance from between the ribs a short distance, two *to four inches, from the line of the spinous processes*; rarely however it makes its way downward before appearing upon the surface. *With disease in* two or three dorsal vertebræ the abscess usually follows the course of the psoas muscle.

Lumbar spondylitis is less frequent than disease in the dorsal, but more frequent than disease in the cervical region. Lumbar spondylitis is usually first recognized by an awkward gait, a limp, and a slight lordosis. The shoulders are thrown backward, one or the other foot is slightly advanced, and the patient walks with care and holds his spine rigid. He is even less inclined than in dorsal disease to forward bending. If there be pain it is usually felt down the anterior and inner surfaces of the the thigh. Most of the symptoms enumerated as characteristic of disease in the dorsal region will be found. Contraction of one or both psoas muscles may come on before the formation of abscess and before the appearance of kyphosis. It is this early involuntary spasm of the psoas muscle, flexing the thigh and limiting its extension before the appearance of deformity that leads to the mistaken diagnosis of hip disease even in the hands of experienced observers.

To test for contraction of the psoas muscle, the patient is placed prone upon the table, the pelvis is held firmly down with one hand while with the other first one and then the other knee is lifted upupward and backward. The freedom with which they can be raised, and the difference in extent, or the extent to which they differ from the normal must be noted. Then with one hand upon the back at about the tenth dorsal vertebra and the other hand lifting both knees at the same time, the rigidity of that part of the spine is noted. It is upon this rigidity that the diagnosis must depend. In normal children the spine can be bent backward so far that the thighs are at nearly a right angle with the upper dorsal spine.

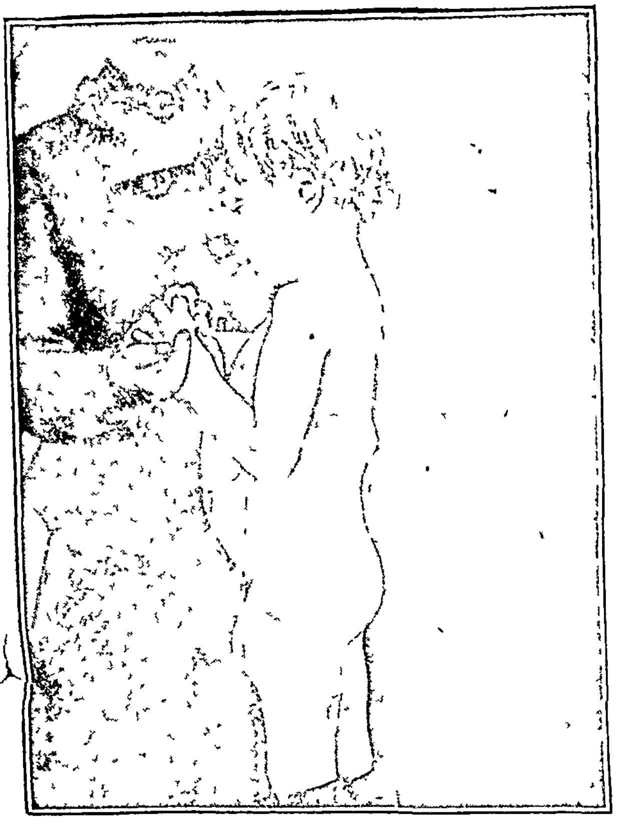

FIG. 15.—Dorso lumbar spondylitis Psoas abscess pointing on the thigh.

Paraplegia is not common. When it occurs it in no way differs from that found complicating dorsal disease. Abscess is frequent, usually following down the course of the psoas muscle and pointing on the anterior surface of the thigh below Poupart's ligament. When the disease is below the third lumbar vertebra the abscess may pass down and point in the buttock; or with disease located in any portion it may pass latterally and point in the loin some inches from the spine.

Differential diagnosis.—A strain may give the early symptoms of spondylitis; for a strain left untreated in a tubercular subject may become a true tubercular spondylitis. A strain should give a distinct history of traumatism.

A rachitic spine closely resembles the "rounded curvature" of spondylitis, the deformity is not infrequently a rigid one, and psoas contraction may also be present; but it will be found only in young children, and the child will nearly always present other evidences of rickets. The mistaking of a rachitic spine for spondylitis however will be of little harm to the patient inasmuch as the rachitic spine demands a rigid supporting brace.

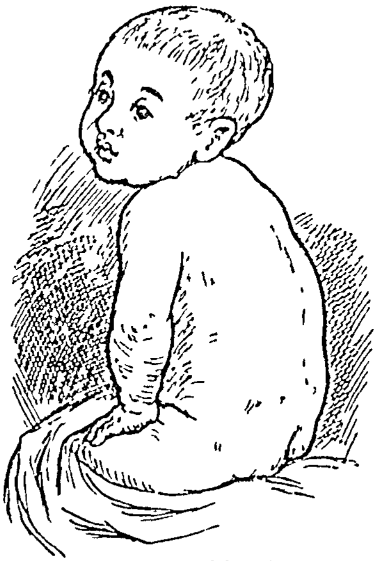

FIG. 16.—Rachitic spine.

Scoliosis—lateral curvature—will not be mistaken for spondylitis in that the curvature is not usually rigid until some time has elapsed and the deformity has become very considerable. On the other hand spondylitis may be mistaken for lateral curvature and the necessary immobilization withheld and possibly exercises advised. A slight lateral curve with or without rotation, if it be rigid is probably a commencing spondylitis. Exercises should be withheld and a support applied. A few months will clear up the diagnosis. Pain is rarely associated with scoliosis; it is the rule with spondylitis, though it should not be forgotten that it may be absent. A careful circumferential outline of the chest may throw some light. In spondylitis it should be practically sym-

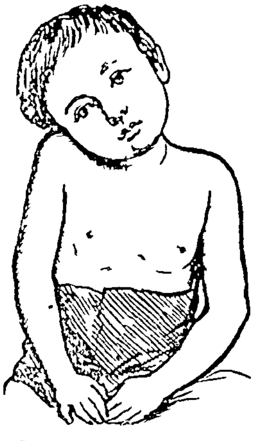

FIG 17.—Torticollis The chin points away from the prominent sterno mastoid muscle

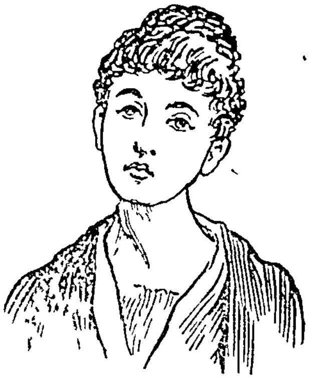

FIG 18.—Cervical spondylitis The chin points towards the prominent sterno mastoid muscle.

metrical; in scoliosis it very early becomes a symmetrical, bulging posteriorly on the side of the convexity of the curve and flattened posteriorly on the side of the concavity; in front the conditions are reversed.

Torticollis—wry neck—is closely simulated at the first glance by spondylitis in the upper cervical region. Still in many cases the diagnosis can almost be made at sight. In wry-neck the chin points *away* from the prominent sterno-mastoid muscle; in spondylitis it points *towards* that muscle, if only one muscle be prominent. In spondylitis the movements of the head are restricted in all directions; in torticollis only in one direction—that which puts the shortened muscle on the stretch.

Hip disease is not infrequently the diagnosis when contraction of the psoas muscle comes on in lumbar spondylitis prior to kyphosis. The patient walks with a limp, complains of pain in the groin or along the anterior surface of the thigh, the thigh is flexed on the pelvis, and attempts to overcome this flexion are resisted by involuntary muscular spasm and give the patient pain. It will however be found that the thigh can be flexed to the normal degree, and that when flexed sufficiently to fully relax the psoas muscle rotation at the joint is free, painless and normal. In a word in lumbar spondylitis extension is the only motion at the hip joint that is restricted by muscular spasm, whereas in hip disease motion in all directions is restricted.

The hyperæsthetic spine, also called irritable spine, if patiently and carefully examined gives no rigidity from involuntary muscular spasm; there is no true distant pain—the pain is located over some portion of the spine itself and is associated with tenderness on pressure. The lightest touch is often complained of more than firm deep pressure. The condition is most frequently found in young women and may have existed unchanged for years. There is no true kyphosis.

Malignant disease of the spine in its early stage cannot be diagnosticated from commencing spondylitis. The history of the case as to hereditary tendency taken together with the age of the patient and his general appearance may make the diagnosis of malignant disease probable, but nothing can be positively said until the progress of the case or the pressure of the tumor clears up the case.

Sacro-iliac disease is not of frequent occurrence, and its early symptoms are obscure. Muscular rigidity to bending in all directions of the lumbar spine will not be found unless the disease is associated with spondylitis of the lumbo-sacral junction. Examination by the rectum should be made in all cases suspected of sacro-iliac inflammation.

The tpphoid spine can of course be found only as a sequela of typhoid fever. There is tenderness on pressure, and on a lateral and forward bending, no special pain in the nerve distribution, no psoas contraction, the onset is sudden, the recovery rapid.

Prognosis.—As to deformity: In the cervical and dorso-lumbar (tenth dorsal to third lumbar inclusive) regions under favorable circumstances the deformity may be reduced if consolidation has not already taken place, and any increase prevented if consolidation has commenced. If no deformity has yet occurred its appearance can of course be readily prevented, and as a rule a rapid cure can be effected. In the upper dorsal region, first to sixth vertebræ, the deformity may be expected to increase under any form of treatment with which we are familiar. From the sixth to the tenth dorsal an increase can generally be prevented, but rarely can any deformity be reduced. When the disease affects the lower lumbar region, the fourth and fifth vertebræ and sacrum, the deformity may be expected to come on and to increase up to a certain point unless the patient be treated continuously in the recumbent posture until consolidation is well advanced. In a word, if the spine can be made straight and kept so sufficiently long for the ossific matter to deposit in the space made vacant by the disease an anchylosis free from deformity, or nearly so, will result. In a few cases more or less restoration of the normal motion is gained.

As to paraplegia: In nearly all cases the paraplegia is due to the pressure of the inflammatory products in the neighborhood of the bony tuberculosis; in these cases recovery may confidently be expected when shrinking of the new material takes place on the subsidence of the inflammation if the patient be kept recumbent for a sufficiently long time. Rarely the paraplegia is due to pressure from a displaced spicula of bone; but there is no evidence that it is ever caused by the acuteness of the angle of the canal. The authors have observed complete restoration of function to the paralyzed limbs in a case where the motor paralysis had been complete for nearly four years, and in another case a recent partial recovery where the sensory paralysis had existed for two years and the motor paralysis for ten.

As to life: Although spondylitis is a most prolonged and serious disease the prognosis as to life, is remarkably good. Only about 8 per cent. of cases receiving proper nursing and treatment die. Of these the cause of death in nearly all is tubercular meningitis, or a general tuberculosis in which the meningial symptoms play a most prominent part.

The duration of the disease in any particular case can not with accuracy be prognosticated. Treatment will be required for at least two years, and may be necessary for twice or thrice that length of time. The duration of the paraplegia is on an average about a year. Relapses of the paraplegia may occur, but are not frequent. The lack of an early diagnosis and of early, energetic and prolonged treatment may be considered as the cause of the deformity which ultimately results in so many cases.

THE U. S. QUARANTINE LAWS AND THEIR SCOPE.

Read before the Chicago Medico-Legal Society, Dec. 3, 1892.

BY JOHN B. HAMILTON, M.D., LL.D.,
SURGEON, FORMERLY SUPERVISING SURGEON-GENERAL, U. S. MARINE HOSPITAL SERVICE.

Mr. President and Gentlemen,—When our learned Secretary suggested to me the writing of a paper on some subject of mutual interest to the members of the Medico-Legal Society, I could only think of the question which for some years had a practical bearing on my acts as an executive officer, and which to-day is of deep interest to every inhabitant of our country, whether denizen or citizen. That question is: How far are our quarantine laws effective in preventing the inroads of disease? And growing from that another inquiry: Are there defects needing legislative remedy?

If my discourse to-night shall seem to dwell on the legal more than upon the medical side of the questions proposed, it is because, as national health officer, I was in position to note the defects existing, and from time to time to propose legislative remedies. The later laws were therefore intended to remedy a defect in the sanitary defenses which on actual trial had been proved to exist.

Permeated with that extreme fear of paternal government that has from the beginning characterized our country, Congress has long hesitated to enact health laws falling under the "general welfare" clause of the Constitution, and has always rather chosen to enact them under the authority given Congress to regulate commerce. Indeed, there has seemed at times a rather pronounced disposition to evade the duty devolving upon Congress in the matter of the public health. Historical study of the dates of the Acts show that they have always been placed on the statute books shortly after a great epidemic. Thus the Act of February 1, 1799, was passed just after the close of the great yellow fever epidemic in Philadelphia, and the Woodworth bill of 1878 was placed on the statute book while the scourge of that year was threatened.

Let us now summarize the existing law. The Act February 1, 1799, provided for coöperation of all Federal officers in maintaining the State quarantines, and extending assistance to State officers. It harmonized the customs service with the quarantine service of the States so far as practicable, authorized the building of customs warehouses at quarantine stations, and in case of the existence of epidemic, the temporary removal of public offices, the courts and prisoners in confinement, to a place of safety.

It is not apparent, from an examination of the text of the Act, that Congress waived its jurisdiction in the matter, or its right to establish quarantine, but the plain purpose of the statute was to aid the State quarantines then in existence.

It is only fair to assume that the question of expediency was taken into account. The country was in infancy, and the public revenues were then needed for public purposes quite remote from quarantines. But so far from waiving its jurisdiction, it was directly implied in the following words: "But nothing herein shall enable any State to collect a duty of tonnage or import without the consent of Congress."

But this topic will be reverted to further on.

April 29, 1878, the Woodworth bill, known as the National Quarantine Act, became a law. In the interval, public sentiment had crystallized rapidly in favor of a National quarantine service, instead of State quarantines. Annual quarantine conventions, called by the mayors of several cities, were held respectively at Philadelphia, Boston, Baltimore and New York, the last named in 1860, and after full consideration it was agreed that Congress should be requested to establish a uniform quarantine system. The systems in vogue at that time varied with the port. The number of days detention, the methods of quarantine practice, were everywhere different, and the sanitary views widely conflicted. Commercial interests were injuriously affected by this lack of uniform practice at the different ports of entry.

The outbreak of the Civil War placed commercial topics in the background for a period of six years, and as commerce began to revive, we find a renewal of the old quarantine questions, but no definite action was taken until the passage of the Act of 1878

This Act really established a National Quarantine; and although no direct penalty was fixed for a violation of its provisions, yet the power given the Collectors of Customs to refuse entry operated to fairly enforce its provisions so far as power over vessel, passengers and cargo were concerned. No direct establishment of quarantine stations was authorized by the Act, but they were implied when the power to frame regulations was conferred on the supervising Surgeon General of the Marine-Hospital Service, acting under the direction of the Secretary of the Treasury, subject to the approval of the President. No appropriation was made to carry the Act into effect.

This Act prevents entry of any vessel or vehicle coming from any foreign port or country where contagious disease may exist, except under such rules and regulations as may be prescribed under the Act.

The law directs all consular officers to immediately notify the Surgeon General in case of an outbreak of an epidemic within their respective districts, and further authorizes and directs that officer to transmit the information thus obtained to National and State Officers concerned with quarantine. A final clause is noticed: "That there shall be no interference in any manner with any quarantine laws and regulations as they now exist or may hereafter be adopted under State laws." This provision was not in the original bill, as it was introduced, nor as it came from the Committee, but was adopted as a Senate Amendment, as a sort of compromise. A certain distinguished Senator from New York, antagonized the bill from its incipiency, and praised the New York quarantine: failing to destroy the bill, he was successful in crippling it in the interest of the accomplished health officer then at the head of the New York quarantine (Dr. Vanderpoel.)

But by whatever means adopted, it has since remained as a limitation on the effectiveness of the Act, and on a recent occasion in which the country was imperiled, this proviso was held to be operative, subsequent legislation notwithstanding.

It has before been stated, that no appropriation was made to carry into effect the Act of 1878. The epidemic of the summer of that year decimated the Mississippi Valley, the city of Memphis especially falling in the shadow of the scourge. Congress, roused to energy, passed an Act February 3, 1879, establishing a National Board of Health, and that body recommended the passage of an Act containing all the provisions of the Act of 1878, but substituting the National Board of Health as the executive authority, instead of the Supervising Surgeon General. This Act was limited to a period of four years, and was clearly experimental. It was approved June 2, 1879.

Before the expiration of the National Board of Health Act by limitation, Congress had grown dissatisfied with that body, and its business methods, and not only refused to appropriate money for its continuance, but made a new appropriation to be used as a contingent fund, in case of epidemic, to be expended by the President of the United States in his discretion in preventing the spread of the disease. While the President might use this fund in his discretion, he was nevertheless bound to use that discretion in accordance with the statutory limitations. He clearly could not use the agency of the National Board of Health, because that body has asked for the money in the regular book of estimates, but Congress had placed the funds in his hands. An examination of the Debates in Congress shows that an amendment offered on the floor of the House to place the contingent appropriation at the disposal of the National Board of Health, had been overwhelmingly defeated. The alternative presented to President Arthur, was to use the existing machinery of the Marine Hospital Bureau, or to donate the money outright in case of need, to local boards of health. He chose to use the government agency, and the yellow fever breaking out on the Texas frontier, the sanitary campaign and the fund was managed by the writer.

The precedent thus set was followed by succeeding Presidents, and in all cases where this contingent fund has been employed, it was directly employed in aid of State and local boards of health, always bearing in mind the limitation of the proviso of the law of 1878. Repeated incursions of yellow fever at some of our Gulf ports, and the measures necessarily taken to prevent the introduction of small-pox from Canada in 1885, induced Congress to take measures for a permanent quarantine establishment, and the writer was asked by the Chairman of the Epidemic Diseases Committee of the Senate, to prepare an Act based on the extensive experience of the Bureau in the matter, and the writer framed the bill which became a law August 1, 1888, which established eight National quarantine stations, directed the procurement of sites, and appropriated a half million dollars for the purposes of the Act. This Act met with no obstruction in its passage, and became a law exactly as introduced, without amendment. It further operated to revive the Act of 1878 by distinct reference to two of its Sections, and imposed a penalty for the violations of its provisions. It provided for the punishment of trespassers on the quarantine stations, and authorized the prosecution by the nearest U. S. attorney. The Act took jurisdiction at once over the entire Pacific coast, by establishing quarantines at San Diego, San Francisco and Port Townsend. Quarantines were also established at Delaware Breakwater, Cape Charles, Sapelo Sound, and two on the Gulf coast. Three State quarantines were passed over—that of Louisiana at New Orleans, New York, and Boston, and at these ports the principal portion of the work is done on the Atlantic and Gulf seaboard. In the introduction of the bill, it was sought to avoid antagonism with the powerful local organizations, and by complete equipment and good management of the Government Quarantines to so demonstrate their superiority that none would finally question the wisdom of a general transfer.

The matter of land quarantine was up to this time untouched by legislative enactment. Its importance had been made fully apparent in the operations in Pensacola in 1883, and in Jacksonville in 1888.

The writer prepared a bill, which after some verbal changes, was transmitted by the Secretary of the Treasury (the Hon. C. S. Fairchild) to the Speaker of the House of Representatives, with a recommendation for its passage. It became a law substantially as transmitted March 27, 1890. Its title is: "An Act to prevent the introduction of contagious diseases from one State to another, and for the punishment of certain offenses." The text of the Act is, after the enacting clause: "That whenever it shall be made to appear to the satisfaction of the President, that Cholera, Yellow Fever, Small-pox or Plague exists in any State or Territory, or in the District of Columbia, and that there is danger of the spread of such disease into other States, Territories or the District of Columbia, he is hereby authorized to cause the Secretary of the Treasury to promulgate such rules and regulations as in his judgment may be necessary to prevent the spread of such disease from one State or Territory into another, or from any State or Territory into the District of Columbia, or from the District of Columbia into any State or Territory, and to employ such inspectors and other persons as may be necessary to execute such regulations to prevent the spread of such disease.

"The said rules and regulations shall be prepared by the Supervising Surgeon-General of the Marine-Hospital Service, under the direction of the Secretary of the Treasury.

"And any person who shall wilfully violate any rule and regulation so made and promulgated, shall be deemed guilty of a misdemeanor, and upon conviction shall be punished by a fine of not more than five hundred dollars, or imprisonment for not more than two years, or both, in the discretion of the court.

"SECTION 2. That any officer, or person, acting as an officer or agent of the United States at any quarantine station, or other person employed to aid in the preventing the spread of such disease, who shall wilfully violate any of the quarantine laws of the United States, or any of the rules and regulations made and promulgated by the Secretary of the Treasury as provided for in Section one of this Act, or any lawful order of his superior officer or officers, shall be deemed guilty of a misdemeanor, and upon conviction shall be punished by a fine of not more than three hundred dollars, or imprisonment for not more than one year, or both, in the discretion of the court.

"SECTION 3. That when any Common Carrier or Officer or Agent or Employé of any Common Carrier shall wilfully violate any of the quarantine laws of the United States, or the rules and regulations made and promulgated for in Section one of this Act, such common carrier, officer, agent or employé, shall be deemed guilty of a misdemeanor, and shall upon conviction be punished by a fine of not more than five hundred dollars or imprisonment for not more than two years, or both, in the discretion of the court."

It is curious that this Act of 1890 should have been completely ignored in the rather animated discussion of last summer, concerning the powers of the President *in the matter of the New York quarantine* and its deficiencies. It will be seen on examination that the Act is more than an inter-State quarantine Act; it provides for the enforcement of discipline at the quarantine stations *and for the* punishment of violations of *any* of the quarantine laws. When attention was called to this Act, the opinion was given verbally, that it was not operative, that it only contemplated inter-State quarantine, and could not be used to supplant a local quarantine, and that it could be used only at a State line.

My contention is that it does give just that authority.

There is now general agreement, I believe, that the original jurisdiction over quarantine rests with Congress; that matter having been settled by the Supreme Court in many cases.

Peete v. *Morgan*, 19 Wallace, 581;

Cannon v. *New Orleans*, 20 Wallace, 577;
State of Pennsylvania v. *Wheeling and Belmont Bridge Co.*, 18 Howard, 421;
Henderson v. *Mayor of New York*, 92 U. S., 259.
Chy Lung v. *Freeman, et al*, 92 U. S., 275;
Railroad Company v. *Husen*, 95 U. S., 465;
Hall v. *DeCuir*, 95 U. S., 485;
Telegraph Co. v. *Texas*, 105 U. S., 460;
Morgan v. *Louisiana*, 118 U. S., 455.

The uniform conclusion being that as the grant of power to regulate commerce is exclusive, "the States cannot exercise that power without the assent of Congress."

Leisy v. *Hardin*, 121 U. S., 119.

Let us inquire what is necessary to set the machinery of the Act of 1890 in operation. The necessary condition is set forth in the Act.

"Whenever it shall be made to appear to the satisfaction of the President that Cholera, Yellow Fever, Small-pox or Plague exists in any State or Territory, or in the District of Columbia, and there is danger of the spread of such disease into other States, Territories or the District of Columbia."

He must be satisfied that the disease exists and that there is danger of its spread. That is the sole condition, Having thus become satisfied, the President can then

"Cause the Secretary of the Treasury to promulgate such rules and regulations as in his judgment may be necessary to prevent the spread of the disease."

There is here no limitation, except that the next succeeding clause provides for the exercise of medical opinion in the framing of the regulations. The Secretary, after having the rules and regulations prepared, can clearly direct their execution. If these regulations should interfere with a State quarantine, that quarantine can no longer operate in conflict with the National regulation. It will be remembered that in the case of Morgan v. Louisiana, the principle was affirmed, that *in the absence of legislation* by Congress on this subject, the State legislation is valid. In the execution of the Act of 1890, there is an example of the enforcement of positive legislation on the subject. As the State quarantine law is only operative in the absence of congressional action, it is, therefore, invalid and need not be considered, and the National quarantine authorities are paramount. Any other construction of the Act of 1890 renders it of no effect and meaningless. It must be assumed that the legislative intent in the passage of this law, was that it should accomplish a certain purpose. That purpose was to prevent the spread of disease, and to make it clear that the power thus conferred upon the Executive Department should not be unnecessarily or uselessly exercised, the operation of the law was made contingent upon disease being present, and in danger of spreading.

The conditions last summer when the health officer of New York sent an impertinent letter to the President of the United States, (if we may believe the current reports in the daily press), were such as to have fully justified such action under the law of 1890, as would have placed the Government in full control of the New York quarantine. Cholera existed at the New York quarantine, and it was afterwards conveyed to the city of New York, necessarily from some defect in the administration of the New York quarantine. Asiatic cholera is known to be naturally foreign to the soil of New York City, and the only place from which it could have come was the quarantine. However, on the question being submitted it was asserted by a high authority, that our action could only be taken at a State line. That our citizens might die on the Normannia, but the Government must not directly interfere. The last Section of the Act of 1878 was relied on to sustain that view. But in case of conflict the subsequent statute must govern, and the Act of 1890 was clearly intended to meet just such conditions.

I may remark, in passing, that we see much in the public prints about the President's "proclamation." The President never made a proclamation on the subject. He simply approved a Treasury department regulation made in pursuance of law. The duty of inquiring into the need of the issue of the regulation and the essence of the regulation itself, was one that naturally devolved on the Treasury Department, and in event of an injudicious regulation having been adopted, the person who gives the advice which led to its adoption is generally held to be responsible by the public, notwithstanding the maxim that "Who does it by another, does it himself."

The issue of a general quarantine regulation under the Act of 1878, necessarily caused adherence to the non-interference Section of that Act. Had the regulations been issued under the Act of 1890, the question of interference with State quarantine could not have been successfully raised. The true interpretation of the Act of 1890 must be found as in the interpretation of all other statutes, that it should be construed according to its plain and obvious import. It is not conceivable that the plain and obvious import of the Statute is to require that any operative measures under it must be taken at the line of an adjoining State; thus, for example, in case the cholera at New York had extended to Jersey City, the measures to prevent the spread of the disease would have to be taken at the Pennsylvania line. Such a course would render the Act absolutely useless, as no intelligent measures could be taken by the Government under such restrictions. There is no circumlocution or ambiguity about the Act; its intent was clear, namely, to prevent the extension or spread of certain contagious diseases. It authorized the adoption of regulations and the employment of the force necessary to carry them into effect. The prevention of the spread of a contagious disease from its existing location, or its suppression at that initial point, is in effect the prevention of its spread from one State to another.

Let us suppose that in Sleepy Hollow, on an island in the State of New York, cholera exists. It would surely be a compliance with the requirement to prevent its spread to the State of New Jersey, if the disease were stamped out or suppressed in Sleepy Hollow. It would simply render subsequent operations useless if we were forced to wait until the disease had spread throughout New York, or if the medical inspector armed with a copy of the Statute of 1890, should calmly proceed to the New Jersey line, and there await the coming of the pestilence. The King who placed his chair on the seashore and commanded the tide to recede from the English coast showed exemplary wisdom compared with such an inspector.

A forced construction of a statute, by which it is reduced to absurdity, is not usually tolerated.

But now that neither cholera, small-pox, yellow fever or plague exists in any part of the

States, the Act of 1890 must remain in abeyance and new legislation must be had if Congress intends to establish uniform quarantine at all ports. In practice it has been found, that wherever the quarantine was a source of revenue, the States have usually desired to retain its control, and it is apparent that should Congress forbid the collection of the fees from shipping by any State or municipality, for quarantine purposes, and provide for their care by the Government, the motive for their retention would disappear. It is proposed at this coming session to introduce a bill that will provide that the President shall by proclamation designate at what ports and places quarantine shall be maintained by the Government, to forbid the collection of any fee for quarantine services—except for board of detained immigrants—and to provide for the extension of existing laws to such quarantines as may be so established. The quarantine inspections are maintained for the public good, their value is to the population in the interior not less than to that of the seaboard. Why should the state be burdened with the necessary expenses of protecting the interior?

The Government alone can protect the whole country. Of what avail is it, said Judge Hornblower in a recent paper, to have a well equipped quarantine at New York, while the one at Philadelphia is inefficient, and there is none at all at New Haven?

Besides the question of efficiency, there is the question of the duty of the Government. The Government is obliged to protect the interior, if protection be demanded. It has no moral right to delegate this plain duty to the State of New Jersey or the State of New York. Congress has not hesitated to pass laws concerning immigration, and establish a harbor patrol in New York to regulate the anchorage grounds in New York Bay. Why should it longer hesitate in the matter of quarantine?

The following is the proposed bill:

An Act to amend an Act entitled an Act to Perfect the Quarantine Service of the United States:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress Assembled:

That the second Section of the Act entitled an Act to Perfect the Quarantine Service of the United States, approved August 1st, 1888, be and the same is hereby amended so as to insert after the words "at the entrance to Puget Sound" the following:

The President of the United States is hereby authorized to designate from time to time such additional places on the coast of the United States for the establishment of quarantines as are in his judgment necessary to maintain a uniform quarantine servic in accordance with existing laws, and that the necessary expense of establishing such additional quarantine stations shall be borne from the contingent appropriation for preventing the spread of epidemic diseases, for the first year, after which such expenses shall be paid from the annual appropriation for the quarantine service; and be it further provided, that it shall hereafter be unlawful for any State or municipal authority to assess upon any vessel of any nationality whatever, any fee whatever for quarantine purposes.

BOOK REVIEWS.

PHYSICIAN'S VISITING LIST, 1893. P. Blakiston, Son & Co. Price $1.00.

This is the veteran of this useful class of publication. In its forty-second year there are the same characteristics of usefulness that have made this the favorite of the profession for nearly half a century.

DOMESTIC CORRESPONDENCE.

To the Editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

Sir:—Within the past few years the State of Texas has received notice from the profession as possessing a warm, salubrious climate, favorable to that class of patients who are suffering from diseases of the chest, and it may be proper to call attention to the peculiar advantages of Central Texas, or the mountain region. Its elevation is from 1,500 to 2,100 feet above the sea level, over 200 miles from the gulf, and below the thirty-first parallel, so it has a dry, warm, genial, bracing atmosphere. That it is good for nearly all diseases of the pulmonary organs is demonstrated by many a stout individual who came here diseased and is now well. The writer selected Central Texas as having the best advantages for a member of his family, and is well satisfied in his choice. No hectic, no expectoration, cessation of cough, a gain in body weight and strength, and exhilarated feelings are the result. The town has not been a "health resort," and its new comfortable houses and hotels are not impregnated with the "lurking germs of disease." Frost rarely comes, and a large proportion of the days in the year can be spent out of doors, fishing, hunting, or geologizing and prospecting for minerals. The soil is sandy and the vegetation is sparse, as in all granite formations, hence the water supply carries less organic or vegetable matter than the water in limestone countries, and a minimum amount of inorganic matter. The rainfall is about 24 inches per year, the wind blows gently every day, and evaporation is rapid, leaving little humidity in the soil or the air. "Northers" occasionally come, when patients must stay in doors, but they do not last long, and never bring snow. All except rainy days can be spent out of doors, and frequently these days have only showers, followed by sunshine. Seldom does a "tropical rain" occur.

Meteorological observations for the past eleven months of 1892 give the following monthly mean temperature and number of rainy days:

	Deg. Fahr.	Rainy Days.
January	49	5
February	53	4
March	60	6
April	73	3
May	75	6
June	90	6
July	94	1
August	88	6
September	84	4
October	76	7
November	68	5

The records were taken at 6 A.M., noon, and 6 P.M., and show an average temperature of 72 degrees and 53 rainy days. Respectfully, C. F. DARNALL, M.D.

Llano, Tex., December 3, 1892.

THE USE OF SALICYLATE OF SODA FOR SPRAINS.—M. Labeeb, without claiming any priority, spoke briefly at a meeting of the Society de Therapeutique of the markedly satisfactory result which he had obtained by the use of one drachm of this remedy in twenty-four hours for a tibio-tarsal sprain. The following morning there was no pain, and in four days there was complete cure. His results were equally good in several cases, whether or not the rheumatic or arthritic diathesis was present.—*La Semaine Medicale.*

SYNTHETIC CHEMISTRY seems to have no limits. The latest product which has been successfully made from coal products is camphor. It promises to be cheap and the specimens submitted respond to the most crucial tests.—*St. Louis Med. and Surg. Reporter.*

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES. . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
NO. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1271, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1271, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, DECEMBER 10, 1892.

PSYCHO-THERAPEUTICS.

This name is used to describe all therapeutics which cures by the intervention of the psychical functions of the sufferer. The first thorough study of this topic was by DR. HAACK TUKE, in which he showed the dominating influence of the mind over the body, and the possibility of curing disease by this power alone. Late authors have divided these remedies into five divisions. The first, *psycho-therapy* is given to all measures which oppose disease by psychical means, or the intervention of psychical functions. The second is *suggestion*, which is the impulse given by one mind to another. This is one of the principle processes by which changes are induced in the mind and organism of the sufferer. The third is called *therapeutic hypnosis*, which signifies normal sleep, induced by suggestion. The fourth means is *hypnotism*, which requires certain abnormal conditions, which when spontaneous are pathological, and when artificial are merely experimental and of little interest in therapeutics. The last has come into great prominence through the studies of CHARCOT, LEIBEAULT and BERNHEIM. Although some wonderful facts have been apparently demonstrated there is a degree of abnormality, with confusion of symptoms and conditions that suggests the empiric stage of the study. Hence, it appears that the efforts to reach the truth along this line of approach are not very promising. The power of suggestion as a remedy where through disease or constitutional conditions the degree of receptivity is strong, is almost marvelous in many cases. This very often extends to hypnotic sleep that is normal. All physicians in a vague, uncertain way, avail themselves of these psychic means, but rarely consider them of scientific interest and worthy of study. DR. VAN EEDEN, of Holland, has in a special study of these measures, declared that the highest attainment of therapeutic art must be sought for in the use of psychic measures. The physician of to-day depends almost entirely upon mechanical, chemical, and electrical remedies, and largely ignores the power of psychic functions. The most advanced studies prove that nearly all the temporary, transient and permanent cures which follow from the use of material remedies, depend more largely on the psychic functions and forces, which are substantially unknown.

The "vis medicatrix naturæ," so frequently mentioned as indispensible is simply this psychic power to withstand hurtful influences, to resist degeneration, and repair injuries. DR. EEDEN urges that hypnotism, clairvoyance, mind reading, and the similar empiric means and measures, used by quacks, be rescued, studied, and made to do service along the line of rational remedies. He considers that psychic therapeutics opens a far wider field for the treatment of disease than the study of bacteriology, and along these two lines the most startling advances of medicine may be expected. All practical physicians recognize the operation of higher and unknown forces in both health and disease. Forces which depress or elate organic functions and antagonize surroundings and therapeutic measures, that can not be foreseen or predicated. Modern psychology shows conclusively that living cells have other than purely chemical and physical qualities. This unknown force is called psychic, and occupies a very important part in the activity of the cell. The study of this has been neglected, and yet every advance of science, both theoretically and clinically, is bringing out innumerable facts, relating to this force, that are not understood or utilized. Psychic therapeutics has begun to be studied along the line of hypnotism. A vast number of people entertain the most extravagant expectations of the value of the mind cure, and christian healing. The power of a suggestive idea is illustrated in every part of the country, no matter what the idea may be. In every consulting room, and sick chamber physicians recognize and use this psychal-therapy, and yet the subject is practically unknown, and without scientific study. DR. HAACK TUKE's work of the influence on the mind on the body, is a most suggestive text-book, and should be read and studied by every physician. Hypnotism can not be ignored, it is a power in therapeutics, although its practical application may be vague and uncertain. Suggestion and all the varied names used to express the psychical force, which is exerted by one over the other, are all dim headlands of an unknown country. A country that belongs especially to the physician and the scientist, and can never be discovered except along the line of exact study and observation.

PROFESSOR VON PETTENKOFER ON CHOLERA.

The *British Medical Journal* for November 19 publishes advance proofs from the *Münchener medicinische Wochenschrift* of an address on cholera by Professor Max von Pettenkofer.

He recalled that many years ago he said that the etiology of cholera was an equation with three unknown quantities, namely: x, a specific germ disseminated by human intercourse; y, a factor dependent on place and time, that he called "local disposition;" and z, the individual predisposition. Places as well as persons often enjoyed immunity, and places which suffered at one time often remained free at another, even when the two factors x and z were present. The determination of y was not as easy as that of the others; but the nature and degree of moisture of the soil had an important influence on this factor.

He thought that the simplicity of Koch's theory commended it to those who only looked at the individual patient, and not at the course of a long series of epidemics. The constant occurrence of the comma bacillus in the excreta of cholera patients indicated that the microbe had something to do with the process, though it was still open to question whether it alone was the cause of the disease.

To test this latter point the Professor obtained some bacilli from Hamburg from Professor Gaffky. A bouillon culture was prepared, and a plate culture from this showed that one cubic centimetre of a thousandth dilution contained numberless comma bacilli, far more than could possibly be conveyed by a man's hand to his mouth. Notwithstanding his advanced age (74), v. Pettenkofer took a light breakfast and two and a quarter hours later, when, according to von Voit's calculations, there could not be so much as 100 cubic centimetres of gastric juice with 0.3 per cent. of hydrochloric acid in his stomach, he took 100 cubic centimetres of a one per cent. solution of bicarbonate of soda; this neutralized the small amount of acid in his stomach and produced a good medium for the development of the cholera spirilli contained in a cubic centimetre of the fresh bouillon culture that he swallowed at a draught. Two days later, severe colicky pains and moderate diarrhœa came on that persisted for six days. During that time the urine was normal, he took no medicine whatever, ate his customary food with a good appetite, pursued his usual avocations without any interruption, and felt perfectly well except for the symptoms mentioned. The stools were examined bacteriologically by Drs. Pfeiffer and Eisenlohr during the duration of the diarrhœa, and were found to be swarming with comma bacilli, yet there were no symptoms of Asiatic cholera. He thought, however, that his experiment might have had a fatal result if it had been carried out in Hamburg, where not only x but y was present in full force.

Professor Emmerich made an exactly similar experiment on himself, with much the same result, except that the colic and diarrhœa were much more severe; otherwise he felt perfectly well.

Von. Pettenkofer considers that these experiments show conclusively that the comma bacillus during its sojourn in the intestines does not produce the specific poison which causes Asiatic cholera, Professor Bauer and Dr. von Ziemssen, both of whom have had considerable experience with cholera, did not think that either v. Pettenkofer or Emmerich had even slight attacks of Asiatic cholera. Von Pettenkofer, while not denying that the comma bacillus has some etiological importance, says he cannot believe it is the x that, without the assistance of y, can cause epidemics of cholera; practically he believes that y, that is the local physical and sanitary conditions, must be attended to in order to make a place cholera-proof.

While these experiments of v. Pettenkofer and Emmerich have eliminated the sources of error that made those of Bochefontaine and Klein fallacious, they have demonstrated what v. Pettenkofer originally denied, that the evacuations of a cholera patient contained the virus at all, either potentially or actually. For in this instance comma bacilli were obtained from the evacuations of a cholera patient, and cultures made from these produced in healthy persons intestinal disturbances with the presence of these bacilli in the diarrhœal stools. And while v. Pettenkofer has made good his challenge of eight years ago to swallow a quantity of comma bacilli, it seems to us that his freedom from other choleraic symptoms was due to the factor z, individual predisposition, rather than to y. In other words we do not agree with the learned Professor that if the same experiment had been performed upon him in Hamburg there might have been a fatal result. In epidemics of cholera only a certain per cent. of the population of a place is attacked, notwithstanding the fact that the "local disposition" is the same for all, though there is always an increase in the number of cases of diarrhœa, so the factor of individual predisposition must be invoked to explain the immunity of portions of the population of a cholera infected city.

And while the ingestion of the cultivations of cholera bacilli in these two cases has proved to be comparatively harmless, it has not been demonstrated that a similar experiment with a number [illegible] men in all sorts and conditions of life would not cause a certain number of fatal cases of cholera.

Symphysiotomy.—The reference to the case of Dr. Barton Cooke Hirst, on page 675 of our last issue, should have been credited to *The Medical News* instead of *The Maryland Medical Journal*.

THE INSURANCE SPONGE.

The sponge is an animal. That question is settled. The vegetarians have ceased to claim it. Like the vanquished party in the recent presidential contest, they surrendered reluctantly, but they surrendered.

"In its simplest form"—so the naturalists inform us—"the sponge is homologically a single animal with the internal structure and function of a colonial organization."

There are many varieties of sponge. The *spongia equina* is the horse sponge of the bath room. The *spongia dura* is the Hardhead found in America. The cup sponge and glove sponge are fine species used in surgery.

All these are marine varieties. "None of them seem to be truly parasitic—that is, capable of living upon the substance of other animals."

But there are land sponges. These also are single animals with the structure and function of organized colonies. Unlike the sea sponges, these land lubbers are truly and with emphasis parasitic—that is, they actually do live upon the substance, the juices, the circulating medium of other animals.

The tramp is a sponge—a combination *spongia dura* and *spongia equina*. He has facial petrifaction united with the peripatetic propensity of the walking delegate.

A sponge possesses the property of enormous absorption and retention; but of its own volition it disburses nothing. Firm compression is necessary to secure disgorgement. *Spongia cerebriformis* is a common enough species, but *spongia corda*—the sponge with a heart—is an exceedingly rare, but not inconceivable variety.

This, by natural gradation, brings us to the subject under consideration.

A Life Insurance Company is a sponge. It belongs to the family of *octopodo millipoda*. It has a head-centre; grasping arms, which extend to immense distances; agents as suckers; and medicine men as tentacles or feelers. Through its agents its sucks into its colonial meshes such an enormous surplus of nutriment that it permits its chief sucker to retain fifty per cent. of the premium blood drawn from the veins of each newly captured victim; while its corpulent head-centre appropriates an amount of this same vital fluid which if transmuted into coin would equal from ten thousand to seventy thousand ducats annually.

The tentacles decide as to the sanitary condition of the victims. They receive scanty pabulum for their services which are, or should be, of greatest value.

The judgment of other medical men (especially those of recognized prominence) as to the ability and fitness of the tentacles is constantly sought by the head-centre. The opinion desired may be of immense importance. It may insure success or ward off disaster. But the insurance octopus sponges the opinion. He disgorges no ducats; he emits not even a worthless thank.

He propounds in a circular a series of questions as to the age of the tentacle whom he purposes to employ; when and where he was educated; his qualifications as a diagnostician; the acuteness of his senses, especially his hearing; the amount of his business; his shrewdness; his mental and moral integrity; his ability to resist the allurements of the willing victim and the anxious sucker; his social and professional standing; and then he craftily pretends that the valuable time spent in answering fully these and many more searching questions is for the sole benefit of the proposed tentacle; while at every moment he knows that the pretense is a false one and employed only to excuse sponging the wished-for information from the meek and complaisant physician.

More than this. He is guilty of the contemptible meanness of promising that if the friendly tentacle shall be maligned and betrayed, the gratuitous betrayal will be guarded sacredly as "confidential."

In the good time coming—slowly coming—some insurance millipod may, by evolution or compulsion, emerge from his spongy condition. Then he will send with his circular questions not only the generous two cent postage stamp, but a suitable fee for careful answers. Then he will frankly acknowledge the truth that the information sought is for the protection of the organization. Then he will be independent enough and shrewd enough to proclaim that (whatever other Associations may sneakingly do) his company is able and willing to pay—and actually does pay—for all services rendered.

When this salutary transformation shall have been effected, the busy doctor will no longer throw, with resentful disgust, the insurance circulars into the waste basket; but he will regard himself as the compensated agent of a cordate and honorable Association which deserves respect and success and whose interests he will gladly seek to promote.

TWO MEDICAL COLLEGE ASSOCIATIONS.

The bulk of the last issue of THE JOURNAL consisted of the most excellent papers presented at the last meeting of the Association of American Medical Colleges, together with the Constitution and By-laws of the above Association and the recently formed association sailing under the title of the Association of Southern Medical Colleges. It is a conceded fact that the maintenance of an association representative of the colleges of this country will tend to subserve their best interests. This has been proved by the history of like associations representative of all branches of the professions and various educational bodies. It remained for the representatives of the leading colleges of medicine to arrive at this conclusion in a period of the last few years only. Consequently there was organized at Nashville, Tenn., in 1889, the present National body with representatives from fifty-four colleges, representing all sections of the country. This Association now contains a membership of seventy colleges. Since the last meeting in Detroit the few representative colleges not then members have signified their intention of being represented at the forthcoming meeting. The *organization of the new college association* is to be deplored from any view that may be taken. There is absolutely no excuse for its existence. It was organized by the representatives of a few colleges located in a sequestered portion of the Southern States. We are of the opinion that the large number of Southern schools at present members of the National Association will retain their membership. The colleges represented in the new association are not recognized as high grade schools. They are not willing to maintain the requirements demanded of the National body notwithstanding the requirements of the latter Association are not as high as they should justly be. We invite the attention of the readers of THE JOURNAL resident in the immediate vicinity of the colleges belonging to the new association, to a perusal of the requirements for entrance examination in these schools. It will readily be *inferred that the people of the South are not desirous* of a very high grade of intellect in their medical men. We are of the opinion that the quickest and most certain method of settling the question of medical education in this country is by efficient medical legislation. The work of a few State Boards fully confirms us in this opinion. The tabulated statistics of the result of the examination of candidates to practice in five different States including 1,950 practitioners, is fully confirmatory of our opinion. We trust the alumni and friends of the colleges belonging to the new association will secure a copy of DR. MILLARD's paper read at the last meeting of the American Academy of Medicine, and see for themselves just what character of work is being done by these schools. In view of the decided action of the American Medical Association at its last meeting we feel it our duty to direct attention to this question. We are of the opinion that the profession as a mass have tolerated the low grade medical college about as long as they will. In the future a more distinct line of demarkation will be drawn between the high and low grade medical college. The statistics of the various State Boards will classify them where they belong and their *clientele* will consist of the scavenger element.

THE court report of the celebrated Alice Mitchell case may be obtained by addressing Dr. F. L. Sim, Memphis, inclosing ten cents in postage stamps.

THE PROPOSITION TO REVISE THE CODE OF ETHICS.—*Dear Sir:*—Members of the American Medical Association having been invited to express their views concerning the proposition to revise the Code of Ethics, I have the honor to state the reasons why, together with many associates, I do not think it wise or expedient to make any change in this admirable system of morals.

1. It would not be wise to alter the code in any particular, because its teachings are salutary, its phraseology is lucid, and its aims are noble; qualities which surely enhance its value as a criterion of medical morals to young physicians entering upon their professional duties.

2. It would not be wise to revise the code; because it does not contain any superfluous statements and because it is the best guide to all physicans in their various relations.

3. It would not be wise to change, even in the slightest degree, the verbiage of the code; because the words are simple, the language is pure and good, and the presentation of the subject is clear and logical.

4. It would not be wise to modify the code; because all its provisions are distinctly stated, and it does not contain any expressions that can be justly condemned or that require modification.

5. It would not be wise to make additions to the code; because it embodies all that is needed in any system of medical morals.

6. It would not be expedient to further consider the revision proposition; because a revision of the code would be likely to cause changes which would be very objectionable to great numbers of members, and which would doubtless excite much discontent.

Continued agitation of this question could serve no good or useful purpose and would occupy precious time, which otherwise might be profitably employed, as in the study and discussion of scientific topics.

I hope that the committee to which the revision proposition has been referred will report against any kind of revision, and that the Association will refuse to entertain further propositions tending to modify the code in any respect, particularly since its spirit has been unequivocally indicated by the most ample and liberal explanatory declarations. A CONSERVATIVE MEMBER.

MISCELLANY.

OFFICIAL LIST OF CHANGES in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from *November 26, 1892, to December 2, 1892.*

Capt. Henry P. Birmingham, Asst. Surgeon U. S. A., is relieved from duty at Boise Bks., Idaho, to take effect upon the expiration of his present leave of absence, and will then report in person to the commanding officer, Ft. Grant, Ariz., for duty at that post.

By direction of the Secretary of War, Par. 3, S. O. 232, October 3, 1892, from this office, directing Major Robert M. O'Reilly, Surgeon U. S. A., to report for duty as attending surgeon in this city on December 15, 1892, is amended to direct him to so report on January 15, 1893.

Capt. Eugene L. Swift, Asst. Surgeon U. S. A., ordinary leave of absence granted is changed to leave of absence on surgeon's certificate of disability, and extended as such two months.

First Lieut. Samuel R. Dunlop. Asst. Surgeon U. S. A., extension of leave of absence granted is further extended one month.

Capt. Junius L. Powell, Asst. Surgeon U. S. A., so much of Par. 2, S. O. 232, A. G. O., Oct. 3, 1892, as directs him to repair to Ft. Monroe, Va., for duty at that post, is revoked, and he will upon the final abandonment of Ft. Randall, S. Dak., report in person to the commanding officer, Jackson Bks., La., for duty at that post, relieving Capt. Wm. C. Borden, Asst. Surgeon. Capt. Borden, on being relieved by Capt. Powell, will report in person to the commanding officer, Ft. Adams, R. I., for duty at that post.

Major William R. Gardner, Surgeon U. S. A., is relieved from further duty at Angel Island, Cal., and will report in person to the commanding officer, Ft. Keogh, Mont., for duty at that post.

The Journal of the
American Medical Association

Vol. XIX. CHICAGO, DECEMBER 17, 1892. No. 25.

ORIGINAL ARTICLES.

MARINE-HOSPITAL RATION.

Read before the Section of Physiology and Dietetics, at the Forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY GEORGE W. STONER, M.D.,
SURGEON UNITED STATES MARINE HOSPITAL SERVICE.

The ordinary articles and quantities of subsistence supplies for ten thousand (10,000) full rations are:

Meat, fresh and salt,	8,000 lbs.
Fish, fresh and salt	2,000 lbs.
Milk	800 gal.
Butter	1,000 lbs.
Eggs	*300* doz.
Lard	300 lbs.
Bread stuffs and other prepared farinaceous food	10,000 lbs.
Vegetables	10,000 lbs.
Fruits, fresh and dry	1,500 lbs.
Tea	100 lbs.
Coffee	300 lbs.
Sugar	1,500 lbs.
Molasses or syrup	25 gal.
Salt	500 lbs.
Pepper	25 lbs.
Vinegar	25 gal.
Pickles	25 gal.

Meat, the first article on the list, especially beef, is the most nutritious of all animal foods. It is easily cooked, very digestible, and perhaps more extensively consumed than any other animal product. The composition of fresh beef—the relative proportions of water, nitrogenous matter, fat and salts—the mean calculated from Pavy's table of lean and fat beef, Yeo's table of three different examples of butcher's beef (very fat ox, moderately fat ox, and lean ox), and Parke's table for calculating diets, including meat of best quality with little fat, like beef steaks, uncooked meat of the kind supplied to soldiers—bone constituting one-fifth ($\frac{1}{5}$) of the soldiers' allowance, and uncooked meat of fattened cattle, and Rohe's table of animal foods, may be given approximately correct, as follows:

Water	69.99
Nitrogeneous matter	19.40
Fat	8.57
Salts	2.04

It is proper to state, however, that the proportion of fat in a very fat ox is given as high as twenty-seven per cent. and Prof. Atwater, as quoted by Billings, places the difference between different parts of well fattened animals, as follows:

Beef, round	8.1
Beef, neck	14.3
Beef, sirloin	14.3
Beef, side	*21.7*

The first table may also be applied to and accepted as approximately correct for moderately fat mutton and pork, though the fat of both these articles of animal food varies from six to forty per cent.

Moderately fat or lean mutton is as easy of digestion as beef but very fat mutton is hard of digestion and unsuitable for invalids.

Pork is not included in the specified ration of the Marine Hospital, but is allowed in the supply table, and while hard of digestion and less adapted than mutton as a food for invalids, nevertheless serves a useful purpose; and salt pork and bacon, like other salt meats are not only popular foods, but from the small proportion of water they contain, also decidedly advantageous from an economic standpoint; and when used with other lean meats, such as rabbit, veal and poultry, and also with other articles rich in nitrogenous matter, as for example in the palatable dishes of bacon and eggs, liver and bacon, and pork and beans, they serve "to establish a proper proportion in the supply of nitrogeneous and carbonaceous material" and the combination is founded on a rational principle.

It is claimed also that in some cases of dyspepsia, salt and smoked meats are comparatively easy of digestion, that they are not so likely to give rise to acid fermentation in the stomach, being less readily decomposed. Niemeyer mentions a remarkable case of this kind—the patient being obliged to limit his diet to lean and smoked ham, sea biscuit and a little Hungarian wine.

FISH.

There are many kinds of fish used as human food. They vary greatly in composition, nutritive value and digestibility. The eel, herring, mackeral and salmon contain large proportions of fat and are exceedingly nourishing to persons of good digestion, but the lighter kinds are, as a rule, more suitable for invalids and persons with delicate stomachs.

Dujardin-Beaumetz, according to Yeo, "divides fish from a nutritive point of view, into three classes, 1. Fish with white flesh, like the whiting and sole. 2. Fish with red flesh, like the salmon, and 3. Fish with greasy flesh, like the eel." The last he considers most nourishing, but least digestible.

The following table of mean composition of white-fleshed fish, including the sole, haddock, carp, white-fish and pike, compiled from different analyses represents in a general way the quality of fish used in the Marine-Hospital ration.

Water	79.90
Nitrogenous matter	17.57
Fat	1.06

Some kinds or varieties of fish are said to improve in flavor and tenderness by being kept for a short time, but as a rule, fish cannot be cooked or eaten too soon after being taken from the water; and salted fish is difficult of digestion and not very nutritious. Fish of all kinds are in the best condition for the dietary just before spawning; during that process, the flesh loses its edible quality and becomes watery and flabby.

The theory that fish is an "intellectual" or "brain food," because of the phosphorus it contains, does not receive much support from recent analyses—good beef being equally rich or *poor* in phosphates. But fish is more easily digested than beef, and, therefore, better adapted for *brain workers.*

Yeo states that Louis Agassiz spoke of fish as food "refreshing to the organism, especiallly after intellectual labor; not that its use can turn an idiot into a wise or witty man, but a fish diet cannot be otherwise than favorable to brain development."

MILK.

Milk is not only a perfect food, containing as it does in proper proportions the four classes or grand divisions of alimentary principles necessary for the support and development of the young of all mammalian animals, but it is the important fluid upon whose analysis the said classification was originally founded. It is the principal constituent of various diets, and is capable alone of sustaining life. It is the most serviceable food for invalids, and as Robert's Well says, "All plans of feeding the sick on liquid food, center round milk." It varies in composition—in the relative proportions of nitrogenous matter, fat, carbohydrates and salts, and is of course, largely composed of water, as shown by the following table of mean composition:

Water	87.20
Nitrogenous matter	3.57
Fat	3.68
Carbohydrates	4.84
Salts	.70

The above table is the mean of three analyses and corresponds closely to the report of the French commission, appointed by the Prefect of Police of Paris. From the analysis of milk, made in various countries the commissson fixed the minimum standard of good milk at—

Water	88.50
Casein, extractives and salts	4.00
Butter	2.70–3.00
Lactin	4.50

Casein is the chief constituent of the nitrogenous matter (the albuminates) but differs from ordinary albumen in not being coagulated by heat. Its fluidity in fresh milk is due to the alkaline or neutral calcium phosphates with which it is combined; but the addition of any acid capable of decomposing or converting the alkaline phosphate into an acid phosphate will cause immediate coagulation or precipitation of casein, and the formation of the so-called curd —the fluid portion from which it separates is called whey. If milk is allowed to stand any length of time, spontaneous coagulation takes place by the development of lactic acid. Warmth hastens this process, and it is a common observation that milk "turns sour" very rapidly in the heat of summer, or during a thunder storm.

The salts contained in milk of average quality amount to about 0.7 of 1 per cent. Calcium phosphate is a considerable and important constituent. Milk also contains chlorides of sodium and potassium, phosphates of soda, magnesia and iron. Butter is another name for the fats or glycerides of milk obtained by the familiar process of skimming and churning, and will be referred to again further on. Lactin is the carbo-hydrate of milk and is known also as lactose or milk sugar.

SKIMMED MILK.

Milk from which the cream has been removed is, of course, less rich in fatty matter than fresh milk, and while more easily digested and useful in certain forms of disease, and as a *starvation* diet in the treatment of obesity, is, I believe, seldom used *intentionally* in the Marine-Hospital ration. It contains, according to the mean of three different analyses by Letheby, Bauer and Church:

Water	89.90
Albuminates (nitrogenous matter)	3.36
Fat	.84
Lactose	5.09
Salts	0.80

WHEY.

As before mentioned, whey is the fluid portion of milk from which the curd has been separated by coagulation. It is sometimes used as a poor substitute for milk and is readily made by adding a small quanity of lemon juice to milk, one or two teaspoonfuls to a pint, and boiling it. Whey contains only a small portion of the elements of the milk, but it is a pleasant drink and more or less useful in certain febrile and stomach affections, and is a popular "cure" at some of the alkaline and salt spring health resorts of Germany and Switzerland. The mean composition of whey, according to Bauer, is:

Water	93.3
Albuminates	0.82
Fat	0.24
Lactose	4.65
Lactic Acid	0.33
Salts	0.65

CREAM.

Cream is that portion of the milk which rises to the surface when the liquid is cooled and at rest. It varies in amount according as the milk is rich or poor, and also according to the means or carefulness by which it is separated. It varies in composition, and the range of variation of the relative quantities of its constituents is so great that no satisfactory table can be given. The mean of two different analyses gives:

Water	56.5
Casein	3.8
Fat	35.8
Lactose	2.6
Salts	1.1

According to Church, the variation of water alone is from 28 to 68 parts in 100. Bauer places the extremes at 22 and 83, and states also that the fat varies from 8 to 70.

BUTTER.

Butter is one of the most popular, agreeable and digestible of the animal fats, and while used almost exclusively as an accessory to other articles or as the necessary grease and flavor in the process of cooking various food products, is *alone* a very valuable food. It is made by the well known process of churning and varies greatly in quality and flavor. It contains a variable amount of casein which is taken up from the milk. Rancid butter is unfit for use, and butter is considered good or bad according, as it contains much or little casein. The rancidity of butter being due to changes in the fat, brought about by alterations in the casein.

The unpleasant and peculiar flavor or taste which some butter possesses is frequently due to the strongly flavored food given to the cows, or which they find in the pasture—as for example, garlic. But another and perhaps the most frequent cause of strong or tainted butter, is the absorption of odorous vapors or volatile flavors from the atmosphere in which it is placed, as for example, the vapors from cheese and meat, and especially from any and every kind of decaying vegetable or animal matter; and these remarks apply to milk and butter alike. The following table shows the average proportions of the most important constituents of good butter, being the mean of *four different analyses:*

Water	10.4
Nitrogenous matter (casein)	.6
Fat	86.5
Carbo-hydrates (Lactose)	0.4
Salts (common salt)	1.1

BUTTERMILK.

The fluid portion of the cream that is left after the butter is separated by the process of churning is a nutritious drink and food. It is easily digested and well adapted for persons suffering from stomach disorders, epecially gastric catarrh, and in the "Milk Cure" of albuminuria and diabetes it *may be* substituted for fresh milk. Niemeyer states that in some patients, fresh milk is not so well borne because it readily curdles in the stomach and forms large, firm lumps, while in the buttermilk, the casein is already curdled, but finely divided. He also quotes the prescription approvingly, "When the patient is hungry, let him eat buttermilk; when he is thirsty, let him drink buttermilk." The *composition* of buttermilk as shown by the mean of *different* analyses is:

Water	90.
Nitrogenous matter (casein)	4.2
Fatty matter (butter)	0.4
Lactine or lactose (*milk sugar*)	4.3
Lactic acid	

EGGS.

Fresh eggs, raw or lightly cooked, are very digestible and highly nutritious. They contain all the elements of the blood and are, like milk, almost a perfect food. The shell consists largely of carbonate of lime, but contains also a small proportion of phosphate of lime and nitrogenous organic matter. It is lined by a delicate membrane which encloses the white of the egg. The yellow or yolk of the egg lies within the white and is also enclosed in a thin membrane. Hard cooked eggs are not easy of digestion if eaten alone, but if taken together with other food and thoroughly masticated they are not very objectionable to a healthy stomach. According to Church "the average weight of a hen's egg, shell and contents is about one and three-fourths (1¾) ounces. It becomes lighter by being boiled, losing a little water." Parkes places the average weight at about two ounces, and calculates ten per cent. shell 22.8 albumen and fat, and 67.2 water, and states that "if an egg weighs two ounces, it contains nearly two hundred grains solids. Pavy, quoted by Yeo, calculates that such an egg would yield 110 grains nitrogenous substance, 82 grains of fat and 11 grains of saline matter. The mean of several analyses shows that the white of an egg has the following composition:

Water	85.2
Nitrogenous matter	12.3
Fat	1.1
Carbo-hydrates	
Salts	.8

The yolk of the egg shows a higher degree of richness. It contains:

Water	51.1
Nitrogenous matter	15.6
Fat	30.8
Carbo-hydrates	0.1

The mixed whites and yolks of hen's eggs, according to Church (shells excluded) contain:

Water	71.7
Albumen and casein	14.
Oil and fat	11.
Membranes and extractives	2.
Mineral matter	1.3

BREAD.

Of all the various cereals used in making flour, wheat is of first importance and yields the best bread. Wheat bread is an acceptable and nutritious food and is more extensively consumed than any or perhaps all other vegetable products. Wheat, like all other articles of food, varies in composition, but the variations in the grain are chiefly limited to the relative proportions of starch and nitrogenous matters. The differences in composition are not only shown between the different varieties of the grain, as for example, the relatively small proportion of albuminoids in the soft, opaque grains of white wheat, and the large proportion in the hard, translucent varieties; but differences also appear in wheat of the same variety, accordingly as it is grown during a dry or wet season. Wheat grown during a fine, dry season contains less starch and more albuminoids than wheat produced in a wet season. The wheat grain contains a middle part or kernel and six thin coverings or coats. The several coats or coverings become thinner and whiter and probably more nutritious as they approach the kernel. Meal is produced by grinding wheat between millstones, and by sifting, winnowing and regrinding, the meal is separated into a number of different products. In some processes of milling the outer coat or fine bran is removed by a previous operation, and in roller milling the germ of the grain is also as a rule removed. In the older process of milling only three different degrees of fineness are recognized—flour, middlings and bran. In the new systems many different grades are produced. Fine flour, seconds flour, tails, sharps, pollards and bran are only a few of the numerous products. In this small classification the first three are considered *flour*, the remainder bran. The thin outside coat of wheat is very indigestible, being largely composed of silica. Bread made from the *finest* wheat flour is as a rule, very digestible, and is almost entirely taken up or absorbed in the process of digestion. It is, therefore, of the greatest value to persons or patients of weak digestion and looseness of the bowels. To obviate or counteract the constipating effect of such bread, bran, rye, cornmeal and molasses are frequently added, forming the different varieties of graham or brown bread. Bread, on the other hand, made from the coarser grades of flour is considered less digestible in proportion as the flour contains the outer or inner scales of the grain, the relative proportions of silicious matter and woody fibre becoming less and less as they approach the center. The indigestibility or low nutritive value of this quality of bread is due to the fact that its nutritive elements are hurried through the bowels by reason of the excessive irritation produced by the indigestible silica, etc., which may also carry away other nutritious material before digestion has been completed, and thereby acutally lessen nutrition. For those who are over-fed and need a laxative, it might be of great value; but if this action is desired, it may be brought about more readily and agreeably perhaps by the use of the whole grain in the form of "cracked wheat" porridge with cream and sugar.

The mean of two different analyses shows that wheat contains approximately:

Water	14.
Nitrogenous matters	11.7
Fatty matters	1.4
Starch, with traces of dextrine and sugar	68.4
Cellulose (vegetable or woody fibre)	2.6
Salts, potash, soda, lime, magnesia, phosphoric acid, etc	1.7

WHEAT FLOUR.

Water	13.93
Nitrogenous matter	9.7
Fatty matters	0.9
Starch, etc	74.2
Cellulose	0.5
Salts	0.6

These tables are of necessity only approximately correct. In some of the harder varieties of wheat—especially those grown in Italy, the relative proportion of nitrogenous matter, gluten and soluble albumen, is greater; and according to Yeo, the proportion of starchy substances in different qualities of wheat ranges from sixty (60) to ninety (90) per cent. Besides the gluten (which is composed of several distinct substances) and the soluble albumen, another nitrogenous substance, termed *cerealin*, a form of diastase or ferment is found in wheat. Cerealin has very active properties, is capable of changing starch into dextrine, sugar, and lactic acid, and is therefore a valuable aid in the process of digestion. But as this substance is found mostly in the outer scales of the wheat grain it is a constituent of the bran and the coarser grades of flour, and the very white or *finest* flour is therefore deficient in this important element; and when in the processes of high milling, the germ of the grain, which contains the diastase proper, is also removed, the resultant flour is beautifully white, free from odor, and superior to any other quality so far as starchy or heat giving matter is concerned, but as a flesh former it must be regarded of less value. The germ is not only rich in nitrogenous matter, but it contains also a large proportion of fat or oil, and phosphoric acid.

"The following analysis," according to Church, "was made on a pure sample of flattened germs from a roller mill."

Water	12.5
Albuminoids. disastase, etc	35.7
Starch, with some dextrine and maltose	31.2
Fat or oil	13.1
Cellulose	1.8
Mineral matter	5.7

This analysis also showed that 60.6 per cent. of the mineral matter was phosphoric acid "so that the original embryos contained 3½ parts per hundred of this valuable constituent of bone," and three times the proportion of nitrogenous matter and more than six times the proportion of fat or oil in the whole wheat grain. He adds, however, "that the albuminoid matter included little or no tenacious gluten, but a considerable quantity of the diastatic ferment. The composition of bran varies in proportion to the number of coatings or coverings removed from the outside of the grain.

The following table, also quoted from Church, shows the composition of "a rather coarse bran."

Water	12.5
Albuminoids and cerealin	13.3
Indeterminate nitrogen compounds	3.1
Starch, with some maltose	43.6
Fat	3.5
Cellulose	18.0
Mineral matter	6.0

The separation of this coarse bran from flour is certainly wasteful, but as an article of diet it is indigestible, not only on account of its mechanical condition, but also by reason of the large proportion of cellulose (woody fibre) and silicious matter it contains. But as before stated, the fibrous and silicious matter is found in the outer coverings of the grain, and if these are first removed and the decorticated grain is then thoroughly ground, the best *(not the finest, whitest)*, flour will be produced.

Bread making may be regarded as the first process in the digestion of wheat flour. The flour is rich in nutritious elements, but in order to be at all palatable or digestible, it must first be mixed with water and salt, made into dough or paste and then baked into firm and porous bread. The porosity is produced by the development or generation of carbonic acid gas within the dough, or by forcing it in from without before the mass is placed in the oven. There are several ways of effecting the process.

First.—By the addition of *yeast or leaven* fermentation takes place and carbonic acid and alcohol are produced. Both of these products escape almost completely during the process of baking; but the carbonic acid gas in its evolution and dissemination through the lump, causes numerous bubbles, and these remain after the gas has escaped and thus the bread becomes porous.

Second.—By the addition of an alkaline carbonate or bicarbonate, the carbonic acid being generated or set free upon the application of heat.

Third.—By the use of *baking powder*.

Fourth.—By forcing the gas in from without, or mixing the flour with water highly charged with carbonic acid gas in an iron vessel under pressure. Bread made by the latter method is called "aerated." The advantages claimed for aerated bread over fermented or yeast bread, are its lightness and dryness and its freedom from the dangers attending the older process of allowing fermentation to proceed too far or not far enough before the *sponge* is placed in the oven, and thus obtaining a sour (acetic acid) taste, or on the other hand a *heavy* loaf. But here the baker's art must *leaven* the process.

Bread varies greatly in digestibility and nutritive value, as well as in chemical composition. The mean of three different analyses is shown in the following table:

Water	37.07
Nitrogenous matter	7.91
Fat	1.39
Carbo-hydrate (starch, dextrine, etc.)	50.14
Salts (including common salt added to the dough)	1.16

OATMEAL.

Oatmeal is a very nutritious food, the richest of all cereals in nitrogenous matters and fat. Its composition, according to Dujardin-Beaumetz, is:

Water	8.7
Fats	7.5
Starch	64.0

Nitrogenous substance	11.7
Salts	1.5
Cellulose and other substances	6.6

It contains a large proportion of indigestible cellulose, but it is easily cooked and is the best food product we possess for making porridge and gruel. It is also sometimes made into cakes, but it is not adapted for bread making, the nitrogenous matter not containing a sufficient amount of adhesive gluten

INDIAN CORN.

Indian corn is produced and consumed in immense quantities in different parts of the world, but principally in North America, the land of its nativity, and especially in the United States. Indeed, its chief preparations, johnny-cake, hoe-cake, mush and milk, and not forgetting hog and hominy are as indigenous as the plant itself.

The whole mature grain is sometimes used as human food, after having been parched and is said to be convenient and valuable to travellers in the Eastern countries. The whole grain is also used in the familiar form of "green corn" and if taken at the proper time and properly cooked, it is not only digestible and nutritious but, if eaten with good butter and salt, delicious.

Corn meal is much coarser than wheat flour and is not so readily cooked, but with proper care and sufficient cooking it can be made very digestible, the only indigestible part being the thin silicious skin or coving. It is not well adapted for making loaf bread on account of the difficulty of baking the central portion, but for Johnny cake, mush and milk, griddle cakes, fried mush and muffins, it is excellent; and when mixed with wheat flour in the preparation of these or some of these *good things*, they become even more palatable and digestible.

Hominy is a popular article of food in some parts of this country, especially in the Southern States. It is the mature grain from which the heart or kernal and skin has been removed. The finer meal cornstarch, is also extensively used and served in the form of *blanc-mange*. The various preparations of corn meal are suitable articles of diet for all persons of good digestion, but in persons with irritable mucous membranes, they are sometimes the cause of intestinal disorders and diarrhœa; while in some cases of torpidity of the bowels, nothing better can be prescribed.

The composition of corn, according to Church, is as follows:

Water	14.2
Albuminoids	9.0
Other nitrogenous compounds	0.3
Starch, etc	66.5
Fat	5.0
Cellulose	3.0
Mineral matter	2.0

According to Parkes the relative proportion of fat is 6.7, carbo-hydrate, 64.5.

RICE.

Rice is the main food of at least one-fourth of the human race. It is grown in nearly all parts of the world where the temperature is high enough for its cultivation. South Carolina is its chief source in this country.

Rice is of less nutrient value than corn, being comparatively poor in nitrogenous matter, and very poor in fat and mineral matter. It consists chiefly of starch, and in composition is not unlike the potato. It is very digestible and is frequently prescribed for patients with weak digestions, and when properly steamed and eaten with milk and cream is nutritious and palatable.

It has the following composition (Church).

Water	14.6
Albuminoids, etc	7.5
Starch, etc	76.0
Fat	0.5
Cellulose	0.9
Mineral matter	0.5

BEANS AND PEAS.

The ripe seeds of many of the leguminosa are used as food; they are all rich in nitrogenous matter. This consists chiefly of vegetable casein or *legumin*, and in quality and nutritive value far exceeds the wheat grain. Beans and peas, owing to the large proportion of albuminates they contain should always be eaten with other foods rich in starch and fat or oil. They should be boiled slowly and for a long time, otherwise they will not be digestible.

The composition of beans and peas is about as follows:

BEANS

Water	14.0
Nitrogenous matter	23.3
Fats	3.
Carbo-hydrates	57.2
Salts	3.

PEAS.

Water	14.6
Nitrogenous matter	22.3
Fats	1.8
Carbo-hydrates	55.8
Salts	2.5

They also contain a small proportion of cellulose. The pods of beans when green and unripe are a popular food, and if properly cooked are very palatable and digestible. Unripe or green peas are also extensively used; they contain a considerable amount of sugar and are easy of digestion.

POTATO.

The potato grows in temperate climates: it is very productive and when properly cooked, palatable and digestible. It is eaten daily by millions of people and was until a comparatively recent time the chief support of a whole nation. It is deficient in nitrogenous matter and salts, but the starch of which it is largely composed is easy of digestion and when eaten with milk or rather buttermilk which is rich in nitrogenous matter, the potato forms a good and economical food.

Potatoes are said to be waxy, or watery, or mealy, according as they are grown in bog lands or in sandy soil; but the potato of sandy soil, and of the very best quality is not infrequently rendered *waxy* or *watery*, and indigestible through the ignorance or carlessness of the cook.

The juice of potatoes contains vegetable acids and their salts and a small quantity of albuminous matter, and the mealiness of the potato depends upon the coagulation of the albuminous constituents and absorption of the acid watery fluid. If the potato is not properly cooked, the granules do not take up the watery fluid, the cells do not become properly distended and separated and the consequence is a waxy, watery or soggy lump.

Potatoes should be boiled in their skins or jackets and in salt water. The boiling must be complete and proceed slowly, otherwise, the starch will be undigested and the albuminates and cellulose will be hard. Steaming is the best method, provided the steam is not super-heated.

The composition of the potato as given by Church and which corresponds practically with the mean of three other analyses is:

Water	75.
Albuminoids	1.2
Extractives, as solanin and organic acids	1.5
Starch	18.0
Dextrine and pectose	2.0
Fat	0.3
Cellulose	1.0
Mineral matter or salts (lime, potass. soda)	1.0

Other roots, tubers, and bulbs used to a limited extent in the Marine Hospital ration are carrots, turnips, parsnips, beets and onions. They all contain about ninety per cent. of water and a relatively small proportion of nutritious substances.

The turnip is the least nourishing; it contains no starch and only 0.5 albuminoids. Its chief constituent is a jelly like substance of the *pectose* group. It contains 1.8 cellulose and 0.8 mineral matter (Church.)

The composition of carrots differs slightly from that of the turnip. The relative proportion of pectose etc., is higher and the carrot also contains a considerable quantity of sugar.

The parsnip is similar to the carrot in composition, but it contains less water, a little more sugar and some starch, the latter not being present in the carrot. The parsnip if properly cooked is a very palatable accompaniment to salt fish or beef.

The beet root contains more sugar and also more cellulose than any of the other roots mentioned. It is cooked in various ways and is largely used in salads and pickles.

The onion is remarkable for its strong smell and taste, due to a minute quantity of volatile oil and sulphur. It is not very nutritious, but more so than the turnip. It is used quite extensively however, both as a vegetable and flavor for other foods, and is a wholesome and palatable food. In its unripe or green state it is used as other green vegetables and also as a constituent of various salads.

The green vegetables, such as cabbage, cauliflower, spinach, tomatoes, lettuce, asparagus and celery, like some of the roots and tubers are of comparatively low nutritive value, but they all contain important salts. They are greatly improved by cultivation and if eaten in their young and tender state before the cellulose has hardened, are comparatively easy of digestion.

FRUITS.

Fruits are important additions to the dietary, their positive nutritive value is low, but they contain valuable salts, a considerable quantity of sugar (notably the grape) and a very small proportion of nitrogenous matter. Many fruits also contain a jelly like substance called *pectin*. Fruit is especially useful in the dietary of persons who have a tendency to constipation and to the gouty condition. The salts upon which their chief value depends are combinations of vegetable acids with alkalies, particularly potash. Fruits are also exceedingly valuable as antiscorbutics.

The popularity of fruits as an article of the dietary is due, however, rather to their refreshing taste and the stimulus they give to weak appetites than to any nutritive value which they possess. Dried fruits are relatively more nutritious; they contain a larger proportion of sugar and less water.

Lemons, oranges, apples, peaches, prunes, raisins and currants are used in the Marine Hospital ration.

SUGAR.

Grape sugar or glucose is found in all sweet fruits, but the sugar contemplated in the food supply table of the Marine Hospital service is the more familiar kind derived from the sugar cane and known as cane sugar. Cane sugar is valuable as a food, but is chiefly used in addition to other foods to sweeten and render them more palatable. It is however not absorbed until through the process of digestion it is converted into grape sugar.

Molasses is the fluid portion left after the crystallized sugar has been separated from the juice.

Salt, pepper and vinegar are used as condiments. Salt (chloride of sodium) is the most important. It is not only useful and necessary as a condiment but it also aids digestion.

According to Church, it "suffers certain changes in the human body, and is not merely taken to be excreted. Its chlorine helps to furnish the hydrochloric acid of the gastric juice and the chlorine of the chloride of potassium found in red blood corpuscles and in muscle. Its sodium forms part of the soda salts, which are among the characteristic consituents of the bile, and of the phosphate of soda of the blood."

Vinegar is extensively used in sauces and salads of various kinds, and in the preparation of pickles.

TEA.

Tea is consumed in the form of an infusion, habitually or occasionally in nearly all civilized nations. It has very little nutritive value, but is a stimulant to the nervous system.

It contains an essential oil and an alkaloid (Theine) upon which its stimulating effect depends. Taken in moderation "a spoonful for each person, and one for the pot" in a weak infusion it proves a refreshing and wholesome beverage. A strong infusion has an inhibitory effect upon peptic digestion.

According to Yeo, "adding a little carbonate of soda, ten grains to one ounce of the dry tea leaf, has the effect of entirely removing the retarding effect on digestion."

Black tea according to Church, contains less theine, essential oil and tannin than green tea. Good average black tea contains

Water	8.
Albuminoids	17.5
Theine	3.2
Tannin	17.5
Chlorophyll and resin	4.5
Essential oil	0.4
Minor extractives	8.6
Cellulose, etc.	34.0
Mineral matter	6.3

COFFEE.

Coffee is not used in the raw state. It is first roasted and then made into an infusion or decoction. It is also sometimes prepared by the process of percolation. The choice varieties are Mocha and Java. Coffee contains an alkaloid, caffein, which is identical with the theine of tea, (by some authors the same term is applied to both) and an aromatic oil. This oil is developed by roasting, and, being volatile, it rapidly changes or deteriorates; for this reason, coffee should not be roasted long before it is used, and the grinding should be done immediately before the infusion is made. Coffee is a nervous stimulant and strong decoctions are decidedly inhibitory to stomach digestion, and should never be taken after meals by persons inclined to dyspepsia; but in this like in all matters pertaining to diet, habit must be overcome gradually.

It is however, proper to add that Roberts in his recent work takes the ground that tea and coffee subserve useful purposes to the human economy; and he defends with a great deal of ingenuity his apparently paradoxical proposition that these beverages are consumed in part with the unconscious purpose of retarding digestion. Nevertheless, he says, "Differences of constitution and personal idiosyncracies have to be reckoned with; and there are frequently good, indeed paramount reasons why individuals should in some particular or other, depart from the general dietetic plan."

Coffee is a very common cause of insomnia, and is occasionally used as an antidote in opium poisoning. In the weaker infusion or decoction, especially if taken with cream and sugar, it is as a rule pleasant and agreeable and decidedly nourishing.

The composition of coffee and tea is very much the same, but they differ somewhat in the relative proportions of their constituents. Perhaps the most important constituent of tea and coffee as prepared in the diet table, is the water—*the sterilized* water. All articles of the dietary contain water, but an additional quantity is necessary not only as a carrier of food in the process of digestion and assimilation, but also as a solvent and carrier of waste products which have to be removed from the body. Water forms about two-thirds of the human body. The proportion of water to perfectly dry food, according to best authorities, should be as four to one. Vital action is impossible without water. Most drinking waters contain mineral matter or salts dissolved in them, chiefly carbonate of lime, but also sulphates, chlorides and nitrates of sodium and magnesium. These salts are also found in vegetable and animal food supplies, but the chloride of sodium in solid food is always deficient in quantity and must therefore be purposely added—while if found in any considerable quantity in drinking water it is evidence of sewage contamination.

In the chemical and physiological classification of food, water and the salts or mineral matter constitute the group of incombustible or oxidized compounds. The combustible or oxidizable group include the carbon compounds, such as starch, dextrine, sugar, and fat, and these are termed "heat givers" or "force producers." Gum, mucilage and pectose are of similar chemical composition though probably of less nutritive value.

The nitrogen compounds or albuminoids constitute another group known as "flesh formers." The chief members of this group are albumin, casein and myosin—also gelatine and chondrine from the animal, and gluten and legumin from the vegetable kingdom.

"One of the main functions of mineral nutrients is to aid in the transference, absorption and elaboration of the oxidizable nutrients—somewhat after the same manner that a scaffolding aids the construction of a building. The same or similar offices are performed in plants by the mineral matters they contain." (Church.)

With the foregoing named articles of subsistence and a few others not specifically mentioned, such as macaroni, vermicelli, sago, tapioca, gelatine, etc., the following diet table was adopted a number of years ago.

I.—ORDINARY DIET-TABLE—UNITED STATES MARINE-HOSPITALS.

Sunday.

Breakfast; Chocolate, 1 pint; bread, 6 ounces; butter, ½ ounce; meat-stew, 4 ounces; fruit sauce, 3 ounces.

Dinner: Soup, 1 pint; beef roast, 6 ounces; potatoes, 8 ounces; other vegetables 4 ounces; rice or tapioca pudding, 4 ounces.

Supper: Tea, 1 pint; bread, 6 ounces; butter; ¾ ounce; mush and milk, 12 ounces.

Monday.

Breakfast: Coffee, 1 pint; bread 6 ounces; butter ½ ounce; meat-hash; with vegetables, 6 ounces; stewed fruit, 3 ounces.

Dinner; Vegetable soup, 1 pint; beef boiled, 6 ounces; potatoes, 8 ounces; pudding with sauce, 4 ounces; bread, 4 ounces.

Supper: Tea, 1 pint; bread 6 ounces; butter, ½ ounce; fruit sauce, 3 ounces.

Tuesday.

Breakfast: Coffee, 1 pint; bread, 6 ounces; butter, ½ ounce; corned beef hash, with potatoes, 6 ounces.

Dinner; Beef soup, 1 pint; beef boiled, 6 ounces; fish, fresh 6 ounces; vegetables, 8 ounces; bread, four ounces; fruit 4 ounces.

Supper: Tea, 1 pint; bread, 6 ounces; butter, ½ ounce; *fruit, stewed 4 ounces.

Wednesday.

Breakfast: Coffee, 1 pint; bread, 4 ounces; butter, 2 ounces; fish-hash with vegetables, 6 ounces.

Dinner: Mutton broth, 1 pint; mutton boiled, 6 ounces; potatoes, 8 ounces; rice pudding with sauce, 4 ounces; bread, 4 ounces.

Supper: Tea, 1 pint; bread, 6 ounces; butter, ½ ounce; cooked fruit, 4 ounces.

Thursday.

Breakfast: Coffee, 1 pint; bread, 6 ounces; butter, ¾ ounce; meat-stew, 6 ounces.

Dinner: Soup (boullion), 1 pint; beef roast, 6 ounces; potatoes, 8 ounces; bread, 4 ounces; fruit, 4 ounces.

Supper: Tea, 1 pint; bread, 4 ounces; butter, ½ ounce; fruit pudding, 4 ounces.

Friday.

Breakfast: Coffee. 1 pint; bread, 6 ounces; butter, ½ ounce; fish-hash with vegetables, 6 ounces.

Dinner: Vegetable soup, 1 pint; meat-stew, 8 ounces; fish, 6 ounces; bread, 4 ounces; vegetables, 8 ounces; fruit, 4 ounces.

Supper: Tea, 1 pint; bread, 4 ounces; butter ¾ ounce; cold meat, 4 ounces.

Saturday.

Breakfast: Coffee, 1 pint; bread, 6 ounces; butter, ½ ounce; mutton chop, 6 ounces; fried potatoes, 3 ounces.

Dinner: Barley soup, 1 pint; mutton boiled, 8 ounces; bread four ounces; vegetables, 10 ounces.

Supper: Tea, 1 pint; bread, 4 ounces; butter, ¾ ounce; rice with sauce, or syrup, 4 ounces.

* Fresh fruit may be substituted in season.

NOTE.—The tea and coffee prepared with milk and sugar. The quantities of the articles of diet indicate them as they are prepared ready to serve.

II.—EXTRA DIET.

Breakfast: Mutton chop or beefsteak, 6 ounces; eggs, 2.
Dinner: Chicken or game, 6 ounces; ale or wine.
Supper: Dry or dip toast, 4 ounces.

III.—MILK DIET.

Breakfast: Hominy or corn-meal mush, 14 ounces; milk, 16 ounces.

Dinner: Rice or tapioca (cooked), 12 ounces; milk, 16 ounces: syrup, 1 ounce; bread, 4 ounces; butter, ½ ounce.

Supper: Cracked wheat or oaten-gritz, (when cooked) 14 ounces; toasted bread, 12 ounces: milk, 16 ounces.

In a note accompanying the ordinary diet table it is officially stated that this "table gives the four classes of solid constituents in substantially the following proportions:

Nitrogenous or plastic material, about one hundred and forty grams; fat, about sixty-two grams; carbohydrates, (starch, sugar, etc.,) about four hundred and fifty grams, and salines, about twenty-six grams; and with about two thousand and two hundred and fifty grams of water. Although these quantities are somewhat in excess of the estimates for "healthy adults at rest," they are none too great for convalescents in whom tissue metamorphosis is being carried on, not only in the interest of repair of present waste from use, but in the interest of repair of past waste from disease, a point which should not be overlooked in the construction of hospital dietaries. In making any changes from the above, the substituted article should be in such quantities and of such kinds as to furnish constituents equivalent to those of the articles replaced."

Recognition is made of the fact that climate and season may render modifications necessary.

In my own experience, substitutions are not so frequent as changes in the relative proportions of some of the articles, notably milk and eggs, which are consumed in greater quantity than given in the supply table, while a reduction is not infrequently made in the meat allowance.

But without regard to any change in the articles or quantities of subsistence, it is proper to state that the quality of the various articles of food supplies as given by the analyses quoted in the foregoing description of each, is probably better than that upon which the official analysis of the diet table was originally based. At any rate, careful calculation of the composition of the articles named shows even larger proportions of nutritive constituents than given in the official note.

REPORT OF FOUR HUNDRED CASES OF INTUBATION OF THE LARYNX, WITH PRACTICAL DEDUCTIONS.

Read in the Section of Diseases of Children, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY F. E. WAXHAM, M.D.,
PROFESSOR OF LARYNGOLOGY, RHINOLOGY AND DISEASES OF CHILDREN, COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO.

Intubation of the larynx has been so frequently and unfavorably compared with tracheotomy that I feel it my duty to report the cases coming under my observation, and to point out some of the reasons for unfavorable results.

It has been my experience, largely through the courtesy of my confreres, to have now operated on something over four hundred cases, with results that might well make any one an enthusiastic supporter of the operation.

It should be remarked that these operations were performed in private practice in a large city and its suburbs, *without selection*, upon all cases dying from laryngeal obstruction, without reference to age, malignancy of disease or unfavorable surroundings. It must be remarked also that a great many of these cases were experimental cases, and many could have been saved with the more modern instruments and with the judgment and skill coming with larger experience.

RECORD OF CASES.

Age (under)	1	year.	12	cases.	4	recoveries.	33⅓	per	cent.
“	1	“	52	“	12	“	22.07	“	“
“	2	“	70	“	18	“	25.71	“	“
“	3	“	69	“	27	“	39.10	“	“
“	4	“	79	“	30	“	37.97	“	“
“	5	“	39	“	18	“	46.15	“	“
“	6	“	25	“	7	“	28.	“	“
“	7	“	25	“	10	“	40.	“	“
“	8	“	10	“	6	“	60.	“	“
“	9	“	6	“	3	“	50.	“	“
“	10	“	5	“	2	“	40.	“	“
“	11	“	1	“	1	“	100.	“	“
“	12	“	2	“	0	“		“	“
“	13	“	1	“	0	“		“	“
“	14	“	1	“	0	“		“	“
“	43	“	1	“	1	“	100.	“	“
“	20	“	1	“	0	“		“	“
“	60	“	1	“	0	“		“	“
			400	cases	139	recoveries	34.75	per	cent.

It should be observed that of these cases 134 were under the age of 3 years, with recoveries amounting to 25.37 per cent., an age at which tracheotomy is rarely successful. It will be observed that in the first hundred cases there were twenty-seven recoveries, in the second hundred thirty-four, in the third hundred forty, and in the fourth hundred thirty-eight. Improved instruments, improved methods of feeding, greater watchfulness and judgment in the management of cases, and the almost universal administration of the bichloride of mercury after the first hundred cases, undoubtedly accounts for the larger ratio of recoveries.

Why is it that we so frequently hear of unfavorable experiences?

1. On account of the difficulty of the operation.
2. Because judgment is not exercised in the selection of the proper tube.
3. Patients are frequently allowed to die from obstruction below the tube which in many cases can be overcome.
4. On account of the absence of careful nursing and the most watchful attention.

Undoubtedly this operation requires more delicacy of "technique" than almost any other operation in surgery. The operation is a far more difficult one than tracheotomy, and few there are who can properly do it without long and special training. It is an operation for the specialist, the expert and those especially dextrous, if best results are to be obtained. Too frequently operators without special aptitude and with no training whatever attempt the operation, the result is disastrous and after a few trials the operation is denounced. In every city this work should be done by one or two operators, who should spare no effort in becoming skilful, and by doing all these operations would soon acquire sufficient experience to insure splendid results. In country districts or in small towns where the operation is not often required, tracheotomy will be found to be far more satisfactory, as no one can become skilful or maintain confidence in doing the operation on two or three cases a year. The result will depend in no small measure upon the judgment displayed in the selection of the proper tube. To introduce a large and tightly fitting tube that cannot be expelled in case of obstruction below it, and to leave the patient in fancied security, is to cordially invite disaster. A loosely fitting tube should be employed, and no harm is done if it is expelled every day, providing the operator replaces it, as he should, gently, skilfully and with no injury. If a tube is rejected several times a day a somewhat larger one should be used. The attendants should always be instructed that in case of emergency from sudden occlusion of the tube the patient should be inverted, and if by shaking the child in this position the tube is not expelled, the finger should be forcibly placed upon the trachea below the tube, when it can be crowded out.

Many a case can be saved by the removal of a tube on the first indication of membrane below it. The indications of partially detached membrane below the tube are very apparent and should not be heedlessly overlooked. The occurrence of a hoarse squeaking cough, with sometimes a decided flapping sound in the trachea, should call for the immediate removal of the tube. When this is done, the expulsive cough that follows will in a great majority of cases expel the membranous cast causing the obstruction. In this manner I have often secured complete casts of the trachea and even larger bronchial tubes, of which these specimens are but a few examples. By a little persistence it will rarely happen that these casts cannot be secured just as effectively as by a tracheotomy.

The success of the operation does not depend simply upon the ability of introducing a tube into the larynx. The careful nursing and feeding and the faithful continuation of treatment, as well as prompt interference in case of emergency, are most important factors in the successful management of a case.

But little difficulty is usually experienced in feeding the patient in the inclined position. In the absence of a trained nurse the physician himself should personally superintend the matter of feeding, otherwise insufficient nourishment will be given. I have often been able to give a half a pint of milk to a patient without difficulty when parents have declared that it was *impossible* to "get anything down." It is extremely important to continue with the same line of treatment after the operation that was instituted before. Of these measures I believe the most important to be the use of the steam atomizer, the internal administration of iron and bichloride of mercury in frequent full doses, and local disinfection. The most efficient local antiseptics and those giving me the greatest satisfaction have been the bichloride of mercury and peroxide of hydrogen.

To recapitulate: In order to obtain the most satisfactory results, the operation should be performed only by those who by special aptitude and careful training are capable of doing it quickly, gently and skilfully.

The greatest judgment should be exercised in the selection of the tube. Emergencies should be promptly met, the case carefully watched, and every detail of management carefully considered.

240 Wabash Ave.

ACUTE BRONCHITIS IN CHILDREN.

Read in the Section of Diseases of Children, at the Forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY C. L. DODGE, M.D.,

OF KINGSTON, N. Y.

Certain anatomical peculiarities of the child's lung deserve attention before entering upon a description of the acute affections to which it is most frequently subject. These peculiarities are of embryonic type, and are present to a greater or less extent up to the fifth year. In the fœtus the bronchial tubes are relatively large, while the alveoli are more bud-like dilatations, "as if Nature had laid out a bronchial tree of generous proportions at the outset, to meet the demands of new-born existence and allow for its subsequent growth." The connective tissue in the fœtal lung is everywhere a delicate meshwork, but loosely retaining the bloodvessels, tending to abundant cell-proliferation, and occupying a far greater relative space than in the adult,—the air vesicles and intervening connective tissue being about equal in extent. The lining membrane of the bronchial tubes, with its rich net work of capillaries, is but loosely bound to the muscular walls, and lies in folds. The alveolar walls are thick, and their structure comparatively loose and yielding; their inner surfaces readily shed and proliferate epithelium, as does the bronchial mucous membrane; moreover, the cells in both instances are relatively larger than those of an adult lung. The blood-vessels, being loosely restrained, readily dilate and encroach upon space properly belonging to the alveoli, and readily cause partial collapse. The thoracic walls are soft and yielding, while the muscles of the throat, bronchi, and chest are relatively less developed and far weaker than in the adult. These peculiarities (which, of course, gradually become less marked after birth as age advances) should be borne in mind, as showing the ease with which serious encroachment upon respiratory space may take place in certain inflammatory conditions.

By the fifth year, in a healthy child, the loose connective tissue has become condensed, properly restraining the capillaries and binding the bronchial lining much more firmly to the walls. New alveoli have been produced, and the proper relative capacity of the air-spaces to the bronchial tubes has been established. The lung has now become anatomically adult, although it still preserves in a measure its faculty of easily shedding epithelium.[1]

Inflammation of the bronchial tubes or bronchitis is one of the most common diseases of early life, and no disease in the nosological list presents greater variations as to type and severity than bronchitis as it occurs in infancy and childhood. It is a matter of common observation for children to pass through the stages of acute bronchitis of mild grade with no medical treatment whatever, and on the other hand we know when abnormally severe it is justly one of the most dreaded diseases of childhood. Bronchitis proper, that is inflammation of the larger tubes, is a more frequent disease than is generally supposed. While I believe with Dr. Morrill that "bronchitis" is credited as a cause of death among children in many cases where the correctness of the diagnosis is open to doubt, I also believe that many cases of bronchitis are diagnosticated, or at least termed inflammation of the lungs. It is well known that bronchitis, among the laity is considered to be a species of throat disease, sub-acute or chronic in character; now to tell many parents holding these views that their child is suffering from bronchitis, when all the symptoms point to a severe acute disease, is to raise suspicion in their minds at once as to the correctness of the diagnosis. Consequently many physicians call every severe case of bronchitis, inflammation of the lungs on general principles. In making out the death certificate many, no doubt, will put down the true cause of death, but when the patient recovers it is from the more serious affection, inflammation of the lungs, the same as it is often with alleged cases of diphtheria; recovery in these cases being a most fortunate result, while in case of death it was no more than was to be expected.

---

[1] Dr. F. Gordon Morrill, in Keating's Cyclopædia, to whom I express my thanks for the free use which I have made of his paper.

Etiology.—The cause of acute bronchitis in most instances is sudden change of temperature from warm to cold, exposure to cold and damp or to currents of air, popularly termed a draught, insufficient clothing, wet or damp feet, sitting on the damp ground, etc. This is not the only disease occasioned by the action of cold; diarhœa and cystitis frequently occur when no other cause can be assigned. Climate undoubtedly plays an important rôle in its production, it being most prevalent in countries which are subject to frequent and sudden changes of humidity and temperature. It is said to be rare in the arctic regions in winter, which would seem to prove that extreme or prolonged cold was not a factor. The Eastern and Middle States furnish many cases of this affection, and in New York bronchitis is much more prevalent during the winter and spring than at other seasons of the year. I believe bronchitis to be more frequent among the children of the poorer classes and the affluent, than among the middle classes. This is owing to the fact that the children of the poor are often insufficiently clothed, poorly housed and fed, and generally neglected so far as protection from vicissitudes of the weather are concerned. With the wealthy it is because of too great care on the part of the parents. Over-heated, ill-ventilated houses are responsible for many attacks of bronchitis. Often in addition to the foulness of the air from natural causes there is added the poison of coal gas from a defective furnace. Children brought up under these conditions, carefully housed and over-clad soon become delicate and fragile, veritable hot-house plants, that are sensitive to the slightest change and susceptible to the slightest chill. The exposure of these children for the briefest time to draughts or chilling winds, is sure to be followed by an attack of bronchitis, croup or tonsillitis. The period of first dentition is one during which many children suffer from bronchial troubles. Jacobi believes that the dampness arising from the constant drooling of some babies constitutes an important cause. Measles and whooping cough are usually accompanied by bronchitis, and in these cases the first named diseases are to be considered the cause of the bronchitis. Sex appears to exert no influence.

Pathology.—The late Dr. Flint sums up the pathology in four lines. Although brief, it covers the ground, and I cannot do better than to reproduce it: “Acute ordinary bronchitis is an inflammation affecting a mucous structure, leading to a secretion of mucous and the production of muco-pus in greater or less abundance. Resolution takes place in this situation without the occurrence of ulcerations. It belongs among the symmetrical diseases.”

Symptoms.—I shall first give a description of this disease as it occurs in infants, and then as we observe it in older children. The symptoms of bronchitis differ much in degree, from a slight cough and indisposition hardly noticeable, to the severe attacks denominated capillary bronchitis, from which few recover. In young babies and children under five the disease usually commences with coryza or in common parlance “cold in the head.” This is not invariably the rule, however, for we sometimes notice abrupt seizures similar to attacks of pneumonia or croup. In addition to the usual symptoms of coryza, such as sneezing, defluxion from the nostrils, etc., there is a dry, harsh, paroxysmal cough, sufficient to prevent the child from sleeping in many cases. The respiration is somewhat accelerated and nursing babies are made cross and fretful when attempting to nurse from the inability to breathe readily through the nose. They are obliged to let go of the nipple from time to time to take a breath, and then resume their meal again. The amount of fever in these mild cases is slight; the temperature perhaps will not rise above 99° F. The pulse is more affected, and from the increased frequency of the respiration and the nervousness and excitement consequent upon the disorder, may rise to 120 or 130 in the minute.

In the more severe cases the child is plainly sick. It wants to be rocked, or carried continually; cries and worries at the approach of strangers, and refuses to play or be amused in any way. The fever in these cases is considerable but must not be estimated by the rapidity of the pulse which is usually 160, and often as high as 200 per minute. The temperature, which alone, is to be relied on in these cases as to the severity of the febrile process rarely reaches 103° F. in simple uncomplicated bronchitis. A fair average would be 101° to 102° F. The skin is dry, hot, and burning to the touch, and the cheeks are flushed. The respiration is very rapid. The cough is dry, harsh and persistent, and after a time somewhat painful. The expectoration—which in babies is a misnomer—is scanty and consists of a little viscid mucous which is swallowed the moment it is coughed up. The tightness persists for some days unless appropriate treatment be instituted, and is a source of much annoyance and suffering. Mild attacks terminate in a week, but where at all severe the disease is apt to last longer, that is the principal symptom, which is the cough. In older children we observe some deviations from the description given above. A child of six or eight is able to expectorate and to describe his feelings. There is no expectoration at first, but after a day or two, especially if treatment has been instituted early, the cough loosens and the phlegm is raised with little effort. The child complains at first of tightness and constriction across the chest, with a scraping sensation beneath the sternum on coughing. After the cough has lasted several days, most children who are old enough to talk, will tell us that they have pain in the stomach—the result of traction on the diaphragm, from the persistent coughing. There is also more or less laryngitis present, with pharyngitis of mild grade in many cases. This gives rise to a sense of tickling in the throat which provokes a desire to cough almost constantly where the local irritation is pronounced. Many cases of bronchitis in children of this age begin as laryngitis and extend down by continuity of structure. The fever is not so high with older children, nor is the respiration so rapid. Capillary bronchitis, so-called, will not be considered in this article as I have limited myself to a consideration of acute bronchitis proper, and stated in the beginning that this is intended to apply only to inflammation of the large bronchial tubes.

Diagnosis.—In mild cases of bronchitis the diagnosis is easy. The characteristic cough attended with but little pain; the rapid breathing; the moderate amount of fever, and the slight constitutional disturbance render the case sufficiently plain. But where the attack is severe, and the smaller bronchial tubes—but not the smallest for then we have another disease, broncho-pneumenia—are involved and great constitutional disturbance is present, the diagnosis becomes more difficult and careful physical examination is necessary to enable us to distinguish between bronchitis and certain other diseases with which it is liable to be confounded. These are croupous pneumonia, broncho-pneumonia, pleurisy and laryngitis occurring singly.

From beginning croupous pneumonia, bronchitis may be distinguished by its gradual rather than its sudden onset; its milder febrile symptoms; its absence of vomiting, epigastric pain, convulsions, and delirium, some of which are present in the majority of cases. In uncomplicated bronchitis there is absence of dulness. Croupous pneumonia, as we know, is attended with consolidation of the pulmonary tissue. Bronchitis is a bilateral or symmetrical disease; in this respect it differs from pneumonia. Râles of all kinds are heard in various portions of the lungs during the progress of the disease except the fine crepitant râle, which is pathognomonic of croupous pneumonia. This, however, is not always present, or at least cannot always be detected in young children. The absence of the expiratory moan is also against pneumonia. Finally, in the latter stages of pneumonia, dulness becomes marked, dilatation of the nostrils and bronchial respiration are present and the distinction becomes manifest. From broncho-pneumonia the differential diagnosis is often difficult, and at times impossible. Broncho-pneumonia, however, is not as some suppose, croupous pneumonia complicated with bronchitis, a sort of combination, so to speak, like the equally vague and uncertain term typho-malarial fever. Broncho-pneumonia is a disease which involves the connective tissue, bronchioles, and air cells. It is very common among children under five years of age, and its mortality is large. It is believed by some of the best observers that a majority of deaths credited to bronchitis are really due to broncho-pneumonia. With this opinion I concur. Now, how can we discriminate between acute bronchitis of severe type and broncho-pneumonia? As stated above, this is not always possible, but attention to the following points of dissimilarity will materially assist us to do so. First, high temperature 102.5° to 103° F., with considerable dyspnœa points strongly to broncho-pneumonia, as does also a marked degree of prostration. Severe constitutional symptoms are rarely present in uncomplicated bronchitis, and when found are of short duration. Ziemssen says that elevation of temperature always takes place if catarrhal pneumonia supervene upon catarrhal bronchitis; in the latter disease it seldom reaches 102.5° F., while in catarrhal pneumonia it often mounts to 105° F. in a few hours. At the same time the pulse becomes more frequent, the face redder, and the child evinces great terror and restlessness, or in severe cases, soon falls into a state of apathy and somnolence.

The physical signs are not always trustworthy. "Theoretically speaking, broncho-pneumonia may be distinguished from bronchitis by the dulness on percussion; practically this aids but little. Dulness on percussion is in children difficult to elicit; and again, a dulness may be temporarily produced in capillary bronchitis by collapse of the pulmonary tissue. There are therefore, no absolute signs of difference," (Da Costa).

A word as to capillary bronchitis. Modern writers, particularly those who study the pathology of this disease carefully and have access to the post-mortem records, are gradually abandoning the term capillary bronchitis, and substituting broncho-pneumonia, as the correct and appropriate designation for this condition. It is to be hoped that writers will soon cease to employ this term as it is misleading and confusing in the extreme. From pleurisy, bronchitis is distinguished by the superficial respiration, the stitch-like pain in the side on coughing and the expiratory moan. Later, physical signs present themselves which are unmistakable. Furthermore, acute pleurisy is not a common disease in children. In laryngitis there is always hoarseness, very little fever and but slight constitutional disturbance, except in the spasmodic form or false croup. Here the peculiar "croupy" cough is pathognomonic. Once heard it is never forgotten. There is also absence of râles.

Prognosis.—In uncomplicated cases of acute bronchitis where the inflammation is limited to the large tubes the prognosis is favorable. Since most cases of broncho-pneumonia, however, begin as simple bronchitis, the bronchioles and alveoli becoming involved later, it is well to give a somewhat guarded prognosis in all cases where the sanitary surroundings are not first-class or where proper care and nursing are unattainable. As stated above it is extremely probable that in very many cases bronchitis is credited as a cause of death among children when the true cause was broncho-pneumonia, often incorrectly termed capillary bronchitis.

Treatment.—While bronchitis cannot be cured by medicine in the sense that malarial fever is cured by quinine, yet I know of but few diseases in which appropriate treatment is followed more quickly by relief from distress and suffering. In mild attacks very little medicine is ncessary but it is quite important that this little be selected with care. Expectorants are remedies that stimulate secretion from the bronchial or laryngeal mucous membrane; in plain English, that loosen or cut the phlegm so that it can be "raised" and expectorated. Great confusion appears to exist in the minds of most young practitioners with regard to this important class of remedies. Among no class of disorders do we see more diversified treatment than in bronchitis, acute and chronic. No better evidence of a man's knowledge of therapeutics can be given, than his ability to prescribe correctly for a cough, be the cause whatever it may. Cough mixtures are frequently constructed on the shotgun principle of hitting something. "Stimulating expectorant" is an unfortunate term. To the beginner, the man without experience, it conveys a false meaning. To stimulate expectoration in the treatment of cough, is the great desideratum in the opinion of the masses, both in the profession and among the laity. But do the so-called stimulating expectorants really increase the secretion from mucous membrane lining the air passages?

Surely squill, senega, ammonia, etc., do not in the early stages; they are simply worse than useless here. Ipecac, tartar emetic and opium, are the remdies in the first stage where the bronchial mucous membrane is swollen, congested and dry, and secretion is arrested or more correctly, is deficient. Nevertheless, a large proportion of the cough mixtures dispensed for a tight cough will be found to contain squill.[2] The opinion has been held from time immemorial that a tight cough forbids the use of opium. No greater error was ever promulgated. To my mind the following quotation from the late Austin Flint is replete with wisdom: no truer words were ever spoken; and the amount of suffering that has been averted by this teaching is simply incalculable. He writes as follows[3]: "Opium is thought by many to be contraindicated in the first stage (bronchitis). It is supposed to interfere with the free secretion of mucous and render expectoration difficult. This is an inference from the effect of opium on the secretions in health; but, so far from these results being produced, opium appears to hasten the second stage. The free secretion of mucous is not the *cause* but the *consequence* of an abatement of the inflammation; and by contributing to the latter, opium virtually acts as an expectorant. Opium, therefore, is indicated in the first stage of bronchitis, as it is in most acute inflammations." This reasoning applies to children equally as well as to adults. Antimony should never be prescribed for very young children as an expectorant, for the same reasons that prohibit its employment as an emetic. The so-called stimulating expectorants as squill, senega, and carbonate of ammonia are inadmissible until free secretion has been established; they are useful in those cases where the circulation is feeble and the patient weak, and where the cough—for there is no voluntary effort on the part of a little child—seems inadequate to the removal of the bronchial secretions. In all severe cases the child should be kept in bed. The temperature of the room should be kept uniform at about 70° F. The child's chest should be well rubbed with a mixture of equal parts of camphorated oil and oil of turpentine as hot as can be comfortably borne. Immediately afterward the chest should be covered with cotton-wadding to which a piece of oil-silk has previously been loosely stitched, this to be retained in position by a muslin band or binder. It should be left on and not disturbed until the child has recovered from all acute symptoms. This is far preferable to the wet and nasty poultices that we were formerly taught to use as a routine practice. In most cases a cathartic is indicated and the old mixture of castor oil and molasses which has been used thousands of times has no superior. Many mothers, however, decline to employ it, and in these cases we must resort to something else. Calomel in $\frac{1}{10}$ grain doses in the form of tablet triturates administered every hour till the bowels act, is a pleasant and effective purgative. It may be supplemented by a dose of citrate of magnesia or compound liquorice powder, in older children. For the cough which is the most distressing symptom, there is nothing to be compared to paregoric in doses proportionate to the age. The following formula has served me well:

℞. Fl. ext. ipecac gtts iv.
Paregoric ʒj–jj.
Syr. tolut ad. ℥jj. M. S.

Take one teaspoonful every two hours till cough becomes looser or less frequent.

This in many cases with the purgative, will be all the medicine required. If, after the use of this prescription for twelve or twenty-four hours the cough does not loosen and become softer, the amount of ipecac should be increased. One-half drop of the fluid extract is not too much to give a baby with a very tight cough and a dry, non-perspirable skin. It need not be kept up however, in such large doses. I do not believe that it is necessary to keep a child "constantly on the verge of emesis" to prevent an ordinary bronchitis from becoming "capillary." It is much better practice to reduce the quantity of ipecac as soon as expectoration becomes easy, which, in the child means only the ability to "raise" easily and without effort. From this time forward a mixture like the one above with the ipecac entirely omitted will be of more service in the majority of cases than any complex formula containig ammonia with one or more of the so-called stimulating expectorants. In those severe cases where the cough is suppressed or in danger of becoming so, then opium is risky for the time being, and we must resort to those remedies that tend to stimulate cough and the respiratory centre, such as ammonia, senega, strychnine or nux vomica, digitalis and liberal doses of alcohol in the form of French brandy or good whisky. Except in these cases they are rarely needed in acute bronchitis. As to emetics, I rarely prescribe them for this disease except under the following conditions. First, in a robust child when seen early with a full, rapid pulse, and a dry, hot skin; here the constitutional effect of the emetic is often markedly beneficial. The nausea induces relaxation and the depressing effect on the circulation relieves the febrile symptoms. The other indication for their employment is where the child's strength seems inadequate to raise or expectorate an accumulation of mucus which threatens suffocation; but even in these cases the emetic should not be repeated too frequently as the depression which follows is ill-borne.

THE RELATION OF DRUGGIST AND PHYSICIAN.

Read at the June meeting of the Ramsey County Medical Society, St. Paul, 1892.

BY CHARLES L. GREENE, M.D.,

LECTURER UPON SURGICAL ANATOMY IN THE UNIVERSITY OF MINNESOTA.

Gentlemen: This nineteenth century is pre-eminently a period of advance in thought and practice. Even theology has been forced to abandon many of her strongholds and adapt herself to changed conditions. Science has exposed many fallacies and unfolded a multitude of new truths. Medicine has upheld her standard well in the front ranks and shown men how to prevent and disperse diseases once deemed a necessary and inevitable penance for the race. In short all departments of learning have conformed to the requirements of the active, inquiring, analytic nineteenth century brain. Whither this spirit of intelligence will ultimately lead us we cannot know, but in medicine, at least, we will set no limits or boundaries to the onward march of its intelligence and the intellectual and moral light which is to illuminate for us all the dark nooks of our chosen and beloved profession. Looking back upon the work of our early predecessors with a feeling of deep wonder, not unmixed with repugnance, we cannot fail to be moved to admiration for the rough and sturdy nature, the patient and profound research which enabled them while groping in comparative darkness to build a broad and substantial foundation for that great superstructure, whose upper limits we cannot now begin to measure. We feel that we labor in a brighter light but yet we find here and there areas of darkness which the sun of our united intelligence has not yet dissipated. We find in our present habits and practice many halting discrepancies which can hardly be reconciled with our steady advance in other directions.

---

[2] From personal knowledge acquired in my early days as a retail pharmacist, I can vouch for the correctness of this assertion. A favorite formula for coughs and colds of all stages with one of the leading physicians of a western city was syrup of ipecac, syrup of squills, and paregoric, each one ounce.

[3] Practice of Medicine, p. 210.

It is to one of these discrepancies that I wish to direct your attention in this paper without desire to pose as a critic and without claim to originality. Simply desiring to place before you facts which appear to me vital and to point out what appears like a parodoxical relation between our physicians and the pharmacists of the present day. In few departments of medicine have our advances during the past century been more marked than in the direction of the preparation and therapeutic application of drugs. Jalap, calomel, blue mass and similar old remedies are fast being relegated to the upper shelves, and newer, more definite and more elegant preparations are superceding the powders, syrups, infusions and decoctions of former days. The organic chemist is giving us yearly new and valuable products the physiological action of which we may often predicate from the grouping of their elements. Physiological chemistry is adding link by link to that grand chain which we hope is to show us eventually the marvellous sequence of changes undergone by body tissues in the various functional activities of the organism as well as the true and ultimate effect of agents administered by us with the view of modifying tissue life and activity. Hand in hand with these investigators works the scientific therapeutist in his endeavor to formulate definite laws for therapeutic application of drugs based upon the researches of his colaborors in the chemical and physiological laboratories. All of these branches of our science are young giants, as yet in their swaddling clothes but already giving abundant promise of a robust and virile manhood. Our professional environment then is continually changing, let us inquire whether we are adapting ourselves to our changed conditions as by right we should. I believe that in many respects we are not. The bonds and fetters of custom and tradition are the most difficult of all to loose. They bind and restrain young and old alike from full freedom of thought and action. Within a few years we have had added to our weapons of offense and defense in our warfare against disease, new drugs potent in action, definite in results, and we have seen evolved from the cruder and more complex drug the infinitely subtle, pure and straight-forward alkaloid. With these have come new methods of preparation which enable us to administer our drugs with greater precision and quickness and with the least hardship to our patients.

In former days the physician could only carry his own drugs from house to house by employing a receptacle of the size of the modern saratoga, and must either dispense by guess or spend a large amount of his time weighing, dividing and directing. Now, however, he may carry all ordinary drugs for emergency or common ailments, in a small and compact case and dispense them as quickly as he could write a prescription, and with almost absolute precision and safety. He will often save life where it was formerly lost by delay, and always save time and money for his clients.

So with his office prescriptions. He was formerly obliged to have either a large drug stock and employ skilled help or waste much time in attempting to combine in himself the functions of physician and pharmacist. He was in danger of either poisoning his patient by overdosing or of being chagrined by utter lack of action in some ancient or improperly prepared product. To him then the druggist came as a true friend and helper. He saved his time and his patience, was a friend in council, and a fountain of authority in the various mysterious branches of pharmacy.

Truly then the druggist should be, and once was, the doctor's aid and faithful ally. He is the representative by descent of men who stood for advance and scientific endeavor. He it was who in past times made a study of so compounding and dispensing as to give the doctor and his patient the best results with the materials at hand. He carried uncomplainingly the immense stock of roots and herbs, metals base and fine, syrups, syringes and all that might satisfy the finical and fancied, or the real and urgent needs of the physician and his patient. Much of his stock was dead and much also of necessity decomposed and inert. Yet upon him the physician relied for a fresh and pure drug. He served as a valuable check for hastily written prescriptions and in many other ways comforted, aided and abetted the long suffering and hard worked medicus. But on his part the doctor returned often the evil for the good, for, not content with prescribing capriciously, he prescribed in characters which would be as Hebrew, Arabic or Chinese to the ordinary reader. He wanted syringes of a certain curve, drugs of an infinite variety and in many ways added his mite to the burdens of the suffering pharmacist. Perhaps it is that the trodden worm will ever turn, perhaps it is the simple logic of events, but the druggist has gradually been getting even with his tormentor. For of late years a surprising change has occurred in the mutual relations of the two men. The druggist is forced to keep in stock a multitude of almost worthless preparations. This means an accumulation of dead stock and that means large prices for drugs dispensed. The charge for a prescription bears almost no relation to the ingredients composing it. It is a charge which has for a basis what the traffic will bear and not the true basis of cost of ingredients. The rise of the great manufacturing houses has taken much of the scientific investigating spirit from the pharmacist and has nearly reduced him to a purely commercial basis. At the same time, strange to say, the educational qualifications required by statutory law are being constantly increased. The sale of patent medicines has been a great source of profit to the pharmacist and injury to the physician and has doubtless had much to do with the increase in druggist's establishments which has reached a point where it threatens ruin to many through excessive competition and helps to turn the pharmacist to desperate means for stemming the rising tide which threatens to overwhelm him. We see our apothecary stores, not dispensing pharmacies but salesrooms for a miscellaneous stock of perfumes, jacknives, toilet articles and such matters as would seem to be but distantly related to the art and science of medicine, and coincidently and of necessity we see large and showy stores and a corps of assistants who seem to be occupied much more with the purely commercial than with the scientific aspect of the traffic. We can but feel that there is actual danger in the blending of these interests. That the man who is subdividing powerful and poisonous drugs should not be subject to interruption to sell a toothbrush or glass of soda water to an urgent customer. Again arises the matter of dead stock. Why do we continue prescribing in powder form where the triturate gives us the same drug already prepared, equal in solubility and exact in dose? Why do we make the druggist a slave to our fancy for prescribing Brown, Jones or Robinsons' open formulæ, or closed formulæ, preparations which are no better than his own but oblige him to buy a large package only a fractional part of which is to be used? We may prescribe hypophosphites and pepsins of different make for each day in the year, and our patient and the druggist will suffer for our poor judgment. It all leads to accumulation of dead stock and that leads to high prices and unreliable products. How often does the doctor prescribe a drug, as cascara sagrada, in proper dose without effect, and upon another occasion get an exhaustive and exhausting action from the same in larger dose bought of another pharmacist. The patient is promised a gentle laxative effect, in both cases he is disappointed and blames his doctor. The doctor knows full well that he has had an inert or bastard product in the first instance and that in the latter a new or reliable preparation was obtained. Then how the fortunate possessor of a successful remedy rejoices in the possession of his prescription. That solitary dollar of his purchases medicine for his immediate and remote family connections and their friends, and ever and anon the simple formula returns to the well to be refilled. To blame the druggist for this at the present time would be unfair because the court of law decides it legal, yet the custom of past years was probably the basis for such a decision. Some things, however, are indefensible; counter prescribing is one of them. Our present laws are utterly insufficient to check this abuse. We should have such a law as would make it easy to convict and imprison all men perpetrating this wrong against the community.

There is a striking incongruity in making a high and rigid legal standard of requirement for the practice of medicine in this State, while at the same time men criminally ignorant of medical science are able to dispense over their counters the most powerful of our drugs for the relief of symptoms which they must necessarily be unable to interpret. Again, there is the manufacture and sale of cure-alls over the counter—cure-alls in some instances based upon the prescriptions of the very men whose patronage the druggist is soliciting.

As regards the sale of patent medicine no comment is necessary. The business is dishonorable to a scientific man if not to all who indulge in it. Most of the articles dispensed are fraudulent, and by false promises and alluring hopes doubtless produce delay and aggravation of symptoms which kill yearly a small army of credulous unfortunates. Of the evil of substitution little need be said for no pharmacist holding himself reputable will permit it. With the second-class druggist we know it as a common, damaging and dangerous practice. Here then we find that, largely in self-defense and through unreasonable competition, the druggist is forced into a position of actual antagonism to the doctor. Both desire certain things which if attained would put us on a common sense footing and redound to the benefit of both alike. The physician desires accurate, rapid, low-priced dispensing. He believes that counter prescribing and patent medicine sales are directly injurious to his patients and to his own business and professional interests, yet he makes little effort to avail himself of modern preparations or aid the druggist who attempts to abolish the two latter evils. The druggist wants for himself the minimum expense for maintenance, viz.: rental, labor and the smallest possible dead stock. There are few medical men who use in regular practice over a score or two of drugs for ordinary everyday prescribing. Yet look at the shelves of our drug stores and you see them piled with hundreds of remedies which are often obsolete, useless and practically worthless, but must be kept to supply occasional demands. There is a large body of manufacturers who are placing their products upon the market daily and advertising them by bringing their articles directly to the physician. A memorandum book, paper cutter or other more or less expensive souvenir reminds the physician that he should prescribe the pills or elixirs of their firms and by no means those of any other. As before stated a man may prescribe hypophosphites or pepsins for every month or day in the year; yet it is fair to presume that any one of those made by our own reliable pharmacists would do all that they might do. Daily we prescribe our calomel and soda in powder to be triturated and divided. The druggist pounds and stirs and measures and weighs. Our patient must submit to a considerable delay and pay an additional sum for the simple prescription. Yet the time and labor of the druggist and the time and patience of our patient might have been saved had the tablet-triturate been prescribed. In the tablet-triturate I firmly believe that we find a partial means of solution of our vexatious and troublesome problem. Here is a means for the physician to secure a cheap, portable, uniformly strong, attractive and accurate form of the drug he desires to use. So also the pharmacist has a form of the drug which would cost him less than two cents a prescription, would require the minimum of space for its display, and would do away with three-fourths of his clerical force. The true druggists have been forced into their present false position, and I believe they would be glad to conform to any reasonable requests from physicians, but as prescriptions are at present written, there is too great an outlay requisite to admit of a sufficient profit from the dispensing trade alone at a reasonable price. There are doubtless too many druggists at the present time and too great competition for the needs of the community. Many of them must inevitably go out of business. We all appreciate the strict business honor and sterling integrity of our best pharmacists. We all have warm friends amongst them. We all desire that a happy solution of our difficulties may arise, but this is the business end of our profession, the point where the interest of the doctor and his patient are both involved, and in business each man must consult his best interest in all honesty. The present system, inasmuch as it forces the druggist into a position of actual antagonism to the doctor, is a false and artificial one. He is our natural friend and ally and we would most heartily welcome a restoration of the old relations, but while we on the one hand, by prescribing our remedies in the present manner, compel large purchases of dead stock, force him to employ a large amount of skilled labor and to rent expensive and spacious stores, so we must expect to see our own interests damaged by the counter prescribing, patent medicine sales and enormous charges for our own prescribed remedies. The day of change is at hand. The younger men particularly are coming to a full realization of the fact that nothing but custom and habit could maintain the present paradoxical relation between physician and pharmacist. It is a significant fact that in the great city of Brooklyn, two-thirds of the physicians are said to be dispensing their own remedies. The time has certainly come when we should throw aside our prejudices and ask ourselves whether we have any moral right or are under any obligation to keep up a system which is expensive for our patients and disastrous to our own business interests, when the means of change are at hand. We shall always need and welcome the true pharmacist, but we should work upon fairer and more reasonable lines. There are men who have endeavored to cut off counter prescribing, but they say that they received little or no encouragement at the hands of the profession. Unless some change is effected the physician will become gradually his own dispenser. For at a cost of a few cents and in as little time as would be occupied in writing a prescription he can give his patient a tangible substance for his money, a palatable and trustworthy remedy, and save him money, time and possible danger, while resting himself secure in the belief, warranted by the guarantee of a great and scientific manufacturer, that he has given his patient a pure and active remedy in exact dose. Almost all the common drugs are now put into the form of tablet-triturates and the physician may even have his own peculiar formulæ so prepared. He has then nearly all the requisites of the ideal preparation, viz.: cheapness, ready solubility, elegant appearance, exact dosage, purity, freshness, uniformity, and last but not least, portability. The cost is nominal. He can prescribe at house or office for all ordinary ailments without recourse to outside sources. I repeat that the druggist and physician must achieve a proper basis for mutual support now or never. No one can deny the right of any man to dispense his own drugs if he chooses. No one will deny, I trust, the advantage which would thereby accrue to the profession and their clients by so doing, unless some radical change is made. Let us try to look at the question frankly and without bias, as we look at others in this great era of progressive thought, and then in some happy way will be found a means rational and sensible of placing druggist and physician in proper relationship while giving to patients the protection and full benefit which they merit at their physician's hands. No doctor wants to do all his dispensing; there will in any event remain sufficient always for the pharmacist in certain lines, but if there were no other way of bringing about the relief of our patients in this matter we ought certainly to dispense for ourselves. I am positive, gentlemen, that these are the views of many here present to-night. Why should such ideas not find free expression? We are under the strongest obligation to advance and protect the interests of our patients, and in doing so, we are true to our profession and ourselves. To allow other motives to influence us, to allow other considerations to tie our tongues, is to prove ourselves recreant knights and unworthy to bear aloft the great and victorious standard which has in the past led the fearless warriors of our profession to their countless victories.

CONTROL OF QUARANTINE BY THE NATIONAL GOVERNMENT.

Read before the Berks County Medical Society, Reading, Pa., Nov. 8, 1892.

BY DANIEL B. D. BEAVER, M.D.,

The appearance of the cholera in New York harbor lately and the measures which were taken to prevent its entry have given rise to discussions of the question as to whether quarantine should be under the control of the National Government.

The question has been argued in the periodicals from legal and sanitary points of view.

In the latter phase it interests us alike as citizens and as physicians. Being physicians we should be sanitarians, and being sanitarians we should not only be interested in a question of such vast importance to the whole country, but feel it our privilege and duty to speak upon it.

With this view I beg to present it to the consideration of this Society, but in doing so will invite attention to such points only as have not been brought out in the discussions which I have seen in the journals.

It has been admitted generally that the health officers of the port of New York succeeded admirably in keeping the cholera out of the country, with the means at their command, but it is also well known that the State of New York and the National Government were not prepared to do the work to the best advantage of all persons concerned. The people who unfortunately came into port with the disease on board were detained unnecessarily and exposed to cruel mental and bodily suffering, while others who also came from infected ports but did not develop the disease on the way were permitted to land immediately after the most superficial and useless examination.

Having been in quarantine two days on a vessel which arrived in New York on the 22d of September, after having been at sea twenty days in consequence of a break in the machinery, with a perfectly clean health bill, excepting one case of typhoid fever, I can speak from experience of the unnecessary delays to which passengers under these conditions were exposed by the hurried and careless examination of the officers. Our vessel arrived at the Quarantine Station at 3:30 P.M., and was boarded by the port physician two hours later. The next morning a young man appeared and passed in review all the first cabin passengers, asking each one the whereabouts of himself and luggage ten days before sailing. I replied that I was on the English Channel on the tenth day, but arrived at Rotterdam the next, and after having been there two days went to England directly by boat, on account of the cholera news from adjacent cities, having, however, left there the day before the vessel which brought the disease to that city got in.

No attention was paid to these explanations, and my name was marked "Rotterdam" on the list. The next morning there came on board a man with orders to fumigate all my luggage, and two other hand bags, one of which belonged to Mr. L. G. Young, of Savannah, and the other to Rev. J. H. B. Brooks, of Oil City. Mr. Young and his wife had been in London some time, but during the ten days before they sailed he went to France for a few days on a business errand, taking along the bag with such articles of wearing apparel as he might need there. He returned to England, met his wife, and they, together with the bag and other luggage, travelled to Glasgow and embarked with 440 other persons, and yet of all their goods only the bag was fumigated. Mr. Brooks had also been in France during the ten days' limit, with his grip sack, and the sack had to undergo purification, while the clothing which he wore was not suspected of containing any of the deadly microbes. My luggage consisted of a trunk and a small satchel. During the voyage of twenty days the trunk laid with half a dozen others in a recess outside of my cabin, and was opened almost daily, often when some of those near it were also open. The satchel was kept in the cabin and things put in and taken out of it several times daily, frequently in the presence of my room mates.

Now, a person who comes from a cholera infected district either does or does not bring with him the germs of the disease. If they are with him he should certainly be disinfected thoroughly in quarantine, and if not, he should as surely escape detention and annoyance. My baggage was as free from infection as if it had come from Greenland, and if it had not been so, there was every opportunity for the microbes to get into any of the parcels around it, with which it was opened and shaken up during the twenty days. What advantage was there then in fumigating mine while all that around it was allowed to pass unnoticed!

The fault in the official inspection was in the lack of thoroughness in the first examination. This was made with too much carelessness and dispatch to avoid error.

Some passengers who had been on the continent during the ten days' limit denied it, and the examiner made no effort to detect the untruthfulness of their statements. If they thought denial requisite is it not probable that they came from infected places, and that their luggage should have received more attention than that which belonged to those who frankly admitted having been on the Continent? Such deception could have been discovered by taking more time, and requiring of each one his hotel bills or other written evidence of location during the ten days.

Then, the fumigation itself was as ineffectual as the preceding proceedures. The trunk and bags were simply laid open in the second cabin lavatory, and exposed to sulphur fumes for one hour, without removal of any of their contents. That such fumigation had a destructive effect upon the cholera microbe, if it was there, will hardly be admitted by any one who knows anything about the subject. Moreover, it has not yet been determined that sulphur fumes will kill the microbe under any circumstances. Surgeon General Wyman says, "sulphur disinfection is inadequate, and it is necessary to rely on the use of pure steam, unmixed with air, at 100 C. (212 Fahr.) for clothing and baggage, to destroy the vitality of the comma bacillus of cholera."* At least, it is safe to say that it has not yet been determined that the microbes of this disease can be killed with less exposure to sulphurous acid fumes than will also disintegrate the animal and vegetable fibre of which wearing apparel is made. Then, in the present state of our knowledge, fumigation without destruction must be regarded as futile, and the discomfort and detention incident to it is an inexcusable injustice to travellers; and fumigation with unnecessary destruction of personal property for the public weal, without ample reimbursement of the individual, should under no exigency be tolerated. Errors in both directions can be avoided by searching preliminary examination of passengers.

It may be said in extension of the severities and inefficiencies of the methods employed in New York harbor that the officials were overworked, and had not time to go into examination of details sufficiently to avoid error, and conseqent injustice to persons, and that the crowded state of the vessels augmented very much the trials in quarantine. But, as vessels are always crowded most when the danger of importing an infectious disease is greatest, and the suffering incident to detentions is always greatest when vessels are crowded, such admission does in no way palliate the faults of a system of quarantine which does not or cannot provide properly for emergencies.

That the system in New York is sadly wanting in efficiency, entailing cruel suffering on some and letting others escape without proper examination is shown on one side by the heartrending tales told by the passengers on the Moravia and the Normannia, and on the other by those on the Ethiopia and other uninfected vessels.

On the other hand it is also true that the sufferings of the uninfected passengers on the infected ships were due primarily to the fact that they were permitted unknowingly to embark with those who brought the disease on board. There the danger to health and life began, and there the first quarantine investigations should have been made. That could probably not have been done by the State of New York because it has no representatives in foreign countries, but the United States government with a consul in every European port, might have extended its protective arm across the water. Possibly there are legal and constitutional objections to such an extension of the functions of the Federal Government, but in a common sense view of the matter they do not appear.

The Federal Government protects citizens of all the States alike in person and property against violence while sojourning in foreign lands. It will exert its whole power to liberate a citizen who has been falsely imprisoned. Why, then, should it not do the same to protect him against danger to health and life from contagious diseases which come to him him through the neglect of others! Why should it not prevent him going on board a homeward vessel in a foreign port in company with infected passengers and merchandise, blindly and without any means of ascertaining the peril he is meeting!

The mortality on the steamship Moravia on its voyage of twelve days equalled that of the great military battles of the age, and the mental and physical suffering associated with the imprisonment of the survivors at sea is equalled in modern history only by the horrors of Andersonville and the Black Hole in Calcutta, and yet nothing was done to prevent American citizens from walking headlong into the death trap.

---

* The North American Review, October, 1892.

On the morning of the day the Ethiopia sailed from Glasgow, I called upon our consul there to learn what provisions had been made against the embarkation of steerage passengers and others from districts affected by the cholera. I was received very courteously and told that he had just then received orders from Washington to request the steamship company to fumigate all the steerage passengers under his supervision. Thinking that possibly further protective orders might have been received from home I repaired to the dock four hours ahead of the sailing time of the vessel, expecting to undergo some sort of examination, perhaps fumigation, but found nothing of the kind. It was said that the steerage passengers were fumigated, but I did not learn where. They, with the second cabin passengers passed in view of a physician as they stepped from the gang plank who did nothing more than look at the motley crowd as it passed him, and ask a few children when they had been sick. He could no more tell whether the seeds of cholera, scarlet fever or diphtheria were in their bags and bundles than whether they had had mutton for dinner.

After such meagre sanitary precautions 442 people were sandwiched into the vessel, only two weeks after the cholera had broken out in the city among a batch of Hebrews who had arrived a few days before the departure of the steamer on which their passage had been engaged. The Ethiopia sailed on the day the President's proclamation, imposing a twenty days' detention in quarantine on vessels with steerage passengers on board, went into effect, with 191 persons in the steerage, and the prospect of being detained twenty days was a constant source of anxiety and fear during the voyage. Would it not have been better if the President had proclaimed that the twenty days' purification must be performed on the other side; that a rigid examination of all persons embarking for this country, requiring written evidence of their whereabouts for twenty days, must be made by the consul; and all persons coming from sections afflicted with the cholera must be disinfected and detained twenty days before sailing, upon pain of indefinite detention in quarantine here.

A thorough preliminary examination and detention, if necessary, on the other side would simply change the place of action; and the change would be advantageous. It would enable all persons to procure evidence of where they were at any time previous to departure, and in case delay were necessary would permit them to remain on land, free from the enervating restraints and nauseating discomfort which are inseparable from confinement on a crowded vessel lying at anchor.

At home the pauper and criminal are shielded against contagious and infectious diseases, while under our present system of quarantine the best citizen abroad with his face turned homeward, perhaps in sight of the Stars and Stripes, is compelled to step upon the broad ocean without the least assurance that pestilence and death are not awaiting him in the foreign filth with which he will be surrounded on the way, and from which he cannot escape, to find the door closed against him for twenty days if he survive to reach home.

In opposition to national control of quarantine, and in advocacy of State rights, it may be said that the traveller abroad can ascertain from the owners of the vessel he proposes to take whether persons from parts where cholera prevails will be on board, and if they deceive him and he suffer loss through the deception he may have recourse at law at home. So he may if he be fortunate enough to get home alive.

But this is the logic of the forum and the courtroom, and not of the hospital and sick room.

As physicians and sanitarians our best work is done in the prevention of illness and suffering; and at present in view of the strong probability of the recurrence of cholera in Europe next summer, it seems the immediate duty of the profession to call the attention of our government to the importance of making provision to meet the dread disease before it reaches our shores, to guard our own citizens in transit on the sea against it, and thus prevent a repetition of this year's mournful scenes in New York harbor.

These ends can be reached best by putting quarantine entirely in the control of the National Government, and extending its regulations to, and enforcing them rigidly, in foreign ports.

HIGHER MEDICAL EDUCATION.

BY W. M. HARSHA, A.B., M.D.,
OF CHICAGO, ILL.

Higher medical education was discussed at the meeting of the South Side Medical Club, October 28, last.

President Harper, of the Chicago University, had expected to be present but was prevented, much to the disappointment of the members of the club.

The principal speaker of the evening was Prof. Wm. E. Quine, a recognized leader in the movement toward higher medical education, who in his usual interesting and impressive manner, traced the advances made in medical teaching during the past two decades. He showed conclusively that the progress has come through the efforts of medical teachers of the more progressive schools, rather than through the demands of the profession at large, or of the public or even of State boards of health. The higher standard of preliminary education now obtaining among medical students was noted among the encouraging signs; and the establishment of an increased number of chairs, and of microscopical, bacteriological and other laboratories here in Chicago, in the more progressive medical colleges, was cited to prove that higher medical education has already been inaugurated; and that we have now in our midst facilities for the scientific study of medicine equal to any found on this continent.

In the discussion that was evoked comparisons were made between the present methods of teaching in this country and those of European countries, which were not discreditable to us when only the better colleges are considered. The average attainment of practitioners however was deplored; and the short and easy courses of study through which a majority have graduated, were pronounced inadequate.

The opinion was general that a higher preliminary education and compulsory four year courses of medical study in which laboratory, manual training, and clinical instruction shall be prominent features, are necessary. Many of these conditions now obtain in the better institutions, while in others there are efforts to raise the standard. This augurs well for the medical graduates of the future and much credit is due to the enthusiastic supporters of the movement. Little was said about post graduate study. A majority of all practitioners of the present have obtained their degrees before the advances noted were made. These men are the conservators of the public health, and to some extent, of the wealth of people.

As such it is their duty to disseminate sanitary and hygienic knowledge and so prevent disease, although in doing so they strike at the source of their income. So often did epidemics occur in times past to decimate populations that some philosophers regarded them as a beneficent provision of nature intended to check over-population. But scientific physicians have sought out the causes of disease in many instances and rational means of prevention were next discovered. Within the past few years the specific causes of suppuration, which gives rise to most forms of blood poisoning, have been discovered. This led to modern aseptic and antiseptic plans of treatment, and as a result the mortality from wounds, injuries and surgical operations has been reduced to a minimum. Likewise the various causes of tuberculosis, typhoid fever, tetanus, erysipelas, diphtheria, and other infectious diseases have been revealed by the microscope, and we have new grounds for belief that means of prevention and cure will be found.

It is estimated that nearly one-third of all children born die before they reach the age of five years—mostly from microbic diseases.

Tuberculosis causes about one-seventh of all deaths. Typhoid fever has caused two thousand deaths annually during the past two years in Chicago alone. From this it will be seen that much remains to be done. The prevailing spirit of scientific investigation must be fostered. It is the duty of the profession to conserve life and assist in the evolution of the race and the attainment of its destiny.

The public which reaps the benefits of scientific medical discoveries has done little in return. The National Government has not consented to establish a department of public health. Appropriations have been insignificant; and legislation aimed at higher standards has been uniformly obstructed in the various States.

In other departments of learning National, State and individual aid of a substantial character has been freely given. In our own State, except in one instance, nothing has been bestowed upon medical teaching so far as I know. Millions have gone to endow hospitals in which the sick may be cared for —little has been given to foster the study which shall aid men to prevent and cure disease.

Theological schools are the recipients of immense sums from time to time. A vast amount of wealth is lavished on art. Half a million is bestowed upon the department of astronomy in the great university now starting. Practically nothing is given to aid enthusiastic men to seek out the causes and cures of disease, to lessen the number of the lame, the halt, and the blind that may be seen on our streets, in the hospitals and asylums. Medical men of scientific bias and training do not acquire large fortunes. Several physicians of international reputation have died in the past three years in Chicago—men who were well known throughout this broad land as medical teachers. So far as I know not one of them left an estate valued at more than fifty thousand dollars. Medical discoveries are not preserved to enrich the authors by regular physicians; but are donated to the profession and so to the public. Commercial medical men who often acquire fortunes are not interested in the scientific aspects of the work and hence little can be expected in the way of endowment for medical instruction from the medical profession. To a considerable extent medical teaching is gratuitous.

Post graduate schools there are that are of incalculable value to the profession. Hundreds of physicians annually avail themselves of the advantages they afford and so the standard of skill and knowledge is constantly advanced. A majority of physicians however, cannot make the sacrifice of business necessary to enable them to devote several consecutive weeks to study; and so they fall behind in the rapid march. Let the University extension plan be applied in post graduate study. If the mountain will not go to Mohammed, let Mohammed go to the mountain. In the city teachers may be provided where groups of ten or twelve can be found who desire to study any special course in their own locality. This in my judgment would give a great impetus to medical study throughout the whole profession. Physicians are willing to pay for such instruction if they can secure it without too great sacrifice of time. In microscopy and bacteriology, which are of the greatest value there is no bar to a proper study in such a manner. In addition to valuable knowledge gained making better sanitarians, diagnosticians, and practitioners, there will spring up more harmony in the profession, and best of all, will come a thirst for more knowledge, which is the most important feature of any education.

58 State St., Nov. 10, 1892.

THE TREATMENT OF SPECIFIC AND NON-SPECIFIC URETHRITIS BY TOPICAL OLEAGINOUS MEDICATION.

BY EUSTATHIUS CHANCELLOR, M.D.

So much has been written and published on gonorrhœa that the medical world has a certain distaste for any new literature on the subject; suffice it to say that the numerous nostrums and panaceas for it, are nearly as common as the disease is prevalent, and hence I feel a sincere misgiving in even attempting an allusion to this subject, not to say anything of the many benefits to be derived by the novel treatment hereinafter described.

More than a year ago, while on a vacation, I was in charge of several hundred men, some of whom were afflicted with the clap, and having but limited means at hand for their treatment, I was in a quandary as to the best method to pursue. The majority of the cases which came under observation were from five to twelve days after incubation, being just about the second period or stage of the disease, which was marked by an abundant, thick, greenish-yellow discharge, considerable pain on micturition, much heat of the caput and body of the organ, with redness of the urethra and meatus.

My attention had long since been directed to the remarkable properties of the chemical compound known as campho-phenique. Its high antiseptic and anæsthetic properties, its freedom from irritant effects, and its complete solubility in bland fats and oils, had early suggested its usefulness in the treatment of many dermatoses, and its tested and proven value in these, in turn, suggested its employment in the condition of things with which I was confronted.

Alkaline baths and a suitable regimen were enjoined, and each individual was directed to use the following injection from four to six times daily, by means of a small blunt-pointed syringe, the contents (about two drachms) being retained from one to two minutes:

℞. Campho-phenique, 1 to 2 drachms.
Benzoated zinc oxide ointment, 1 ounce.
Sweet oil sufficient to make 4 ounces. M.

This in a short time caused an amelioration of the symptoms and a rapid convalescence.

The constant and almost daily use of campho-phenique has suggested several beneficial oily combinations. When properly prepared and used judiciously, the effects are as startling as the cure is speedy and permanent. A satisfactory experience has demonstrated that this agent, when mixed with oils or fats, is one of great value in venereal diseases, having properties which, for the sake of brevity, may be expressed thus:

1. It is an antiseptic, a local anæsthetic and, in proper dilution, entirely innocuous to the tenderest urethra.

2. The vehicle should be albolene, benzoinol, any bland oil or fat, or an ointment.

3. As an injection it appears to palliate the sensitiveness of the mucous membrane, and to act as a varnish over the entire tract, thus allaying the scalding and irritation subsequent upon micturition. Pain is greatly mitigated after the first few injections, each of which should be retained for several minutes.

4. Campho-phenique readily mixes with aristol or iodoform, should such a combination be desired. One scruple of either substance may be added to each drachm of campho-phenique. But small amounts of such mixture should be ordered, as they must be freshly made every day or two. It is well to remember that the antiseptic index of campho-phenique is many times that of either iodoform or aristol.

5. Campho-phenique injections, as described above, have proven highly efficacious and satisfactory in cases of erosive granulations, ulcers and indurations of the urethra. The troublesome discharges due to inflammation of the lacunæ of the urethra succumb quickly to such injections, and danger of subsequent stricture is very much lessened.

6. The duration of the disease is remarkably lessened by the described treatment, the average length being from twelve to fifteen days, and could, I think, be further shortened by increasing the daily number of injections.

The following are given as examples of the mixtures spoken of above (4):

℞. Campho-phenique, ½ to 1 drachm.
Iodoform, 1 to 1½ scruples.
Albolene, 2 ounces. Mix.

℞. Campho-phenique, ½ to 1 drachm.
Aristol, 1 to 1½ scruples.
Benzoinol, 2 ounces. Mix.

℞ Campho-phenique, ½ to 1 drachm.
Bismuth subnitrate, 2 drachms.
Olive oil, 2 ounces. Mix.

PURULENT BRAIN DEPOSITS, AND PHLEBITIS AND THROMBOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

BY FRANK ALLPORT, M.D.,
OF MINNEAPOLIS, MINN.,
PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLOGY IN THE UNIVERSITY OF MINNESOTA, ETC.

(Continued from page 691.)

Brain abscesses are never a primary disease. They are always the result of traumatism, pus contact, or pus migration, and are usually caused from otorrhœa. They affect the white rather than the gray matter, and being usually found in the temporal lobe—in which are neither motor or sensory nerve-tracts—distinct localization symptoms are apt to be conspicuous from their absence. This is equally true of abscesses in the frontal lobe, which may be entirely destroyed, without producing special signs.

Mr. Field says that "The more acute forms of abscess, give rise to the signs usually attributed to meningitis or encephalitis, while the more chronic ones give rise to no symptoms whatever, until the abscess extends sufficiently near the surface of the brain to light up an inflammation of the membranes, when it becomes suddenly revealed. The probability is that chronic abscesses may exist for years without trouble. It is probable also that recoveries from such abscesses have taken place, the pus undergoing fatty degeneration, becomes quiescent, the fat is re-absorbed, and the fibroid sac shrinks and contracts upon a cretaceous residue."

Abscesses that develop slowly are often encapsulated. Acute abscesses are not usually encapsulated. It is possible that a larger proportion of abscesses are encapsulated than would appear, owing to the possibility of a primary retention of pus within its walls, and a subsequent disintegration of the capsule, with a diffusion of the contents.

The symptoms that may be expected in cerebro-aural pus deposits are often vague and indefinite. This may be attributed to the frequent lack of brain pressure, owing to the many places where pus may lodge, and accumulate, even in large quantities, without materially compressing sensitive brain substance. It may also be due to the fact that brain abscesses following ear diseases, are usually located in lobes containing no sensory or motor nerve tracts, and in consequence enormous destruction of their substance may take place without active symptoms supervening. An explanation may also be found in the fact that a constant draining of the abscess occasionally occurs through the middle ear, or mastoid bone, by spontaneous or operative openings. An abscess may approach in this insidious manner, without sounding a note of warning, until suddenly it will burst into sensitive portions of the brain, and death may occur before one is fully aware of danger, although a majority of these cases have symptoms to which brief allusion may be made.

The patient usually has suffered from a chonic otorrhœa. The discharge may be profuse, unaccountable, and uncontrollable, or it may, for some reason, either spontaneously or from injudicious treatment, suddenly materially lessen or nearly cease, and it is under such circumstances that symptoms occur, pointing to brain complications. We note primarily continuous severe pain in the head, focussing in one particular spot corresponding to the principal seat of of lesion, and we would consequently look for pain in the side of the head, in case of a complication of the temporal or middle lobe, and in the occiput when the cerebellum is involved. The pain becomes worse during febrile exacerbations, and pain in the affected ear will also be frequenly noticed. The mastoid is often tender, painful and swelled, while nausea and vomiting are often present, and probable constipation of the bowels. Rigors, all the way from a chilly sensation to a pronounced chill may be present, and when seen, should instigate active measures. No positive reliance can be placed on the sudden accession of febrile symptoms, as the same conditions might be found in a case of pure otorrhœa, with pus retention.

It is a generally accepted opinion that cerebral abscesses produce a sub-normal temperature. These records hardly endorse this view. A high temperature is recorded eight times, a medium temperature *forty-two times, and a sub-normal temperature only* twice. In one hundred and fifteen cases the temperature is not mentioned, and in these latter cases it is fair to presume, that the temperature was not a conspicuous feature, or it would have been noted, especially had it been sub-normal. The post-mortem reports show 98 cases where brain abscesses were found, and only two cases, as before mentioned, are recorded where a sub-normal temperature existed. In both these instances, however, it is but fair to observe, a brain abscess was disclosed after death.

The conclusion therefore, is forced upon us, that while a sub-normal temperature *may* by indicative of a brain abscess, when found in such cases, we need not feel that a sub-normal temperature *must* exist, in all cases of brain abscess.

It will be observed also, that a high temperature is recorded only eight times. In these cases, the autopsies did not show brain abscess to be the predominating feature. Almost invariably, thrombi in different locations, and extensive necroses were the leading post-mortem appearances. From all we can learn, therefore, the temperature and pulse are *moderately* elevated in cases of auro-cerebral abscesses. Occasionally the pulse has been found very sluggish. Toynbee has recorded one case where the pulse beat was from 16 to 20, and Wreden has observed one case where it was only 10 to the minute.

Delirium, partial or complete unconsciousness, vertigo, somnolence, and convulsions are noticed in most cases, and coma is generally one of the last symptoms observed. The different forms of paresis and paralysis are often seen, and are chiefly noticed in the arms, legs, face, lids, and by strabismus, dilitation of the pupils, diplopia, paralysis of the auditory nerve, and incontinence of urine.

Inasmuch as the seventh nerve passes through the tympanum, in the Fallopian canal, parts supplied by it are apt to be paralyzed, when tympanic necrosis is an element in the case.

Attention should be directed to inflammation and paralysis of the optic nerve, as it is a symptom that is not often sought, and one to which some authors attach much importance. It would probably be found oftener if the ophthalmoscope were more frequently brought into requisition, and this instrument should certainly be used when amblyopia or amaurosis are present, as they are occasionally.

Truckenbrod regards aphasia, as a symptom of invasion of the temporal lobe, and Wernicke claims that aphasia indicates a disturbance in the posterior 3d of the 1st left temporal convolution.

It is undoubtedly true that in the cases I have grouped together, aphasia is present *only* in those cases where there was a purulent involvement of the left temporal lobe. The records do not show, however, whether it occurred in the posterior 3d of the 1st left temporal convolution, but it must not be forgotten that distinct abscesses were found by *post-mortems* to be present in 40 temporal lobes, of which a good proportion were on the left side, and in but six of such instances, was aphasia present. This remark does not include those cases of pus *diffusion* over the temporal lobe.

The question of a differential diagnosis with brain tumor may arise, in the history of such cases. One very important point in enabling us to arrive at a conclusion in such an instance, is the fact that in brain tumor all the symptoms are quite certain to be constant, with an ever increasing tendency to become worse; while in abscess, the symptoms usually become worse during febrile excitement, and have a vacillating course.

Von Bergman says that the nearer the abscess approaches the posterior division of the frontal convolution, the more apt are we to observe strabismus, disturbances of speech, and irritation or paralysis *of the facial nerve.*

From my review of these 169 cases, I have ascertained *the symptoms recorded as occurring in cases* where the autopsies have shown the cause of death to have been, the *intra-cranial presence of pus, outside of the veins and sinuses.* They are as follows:

Deafness	9	Aphasia	5
Head pain	38	Stupor	12
Ear pain	16	Somnolence	7
Chills	16	Tinnitus aurium	2
Temp. sub-normal	2	Insomnia	1
" medium	7	*Meningitis*	4
" high	2	Optic neuritis	3
Pulse sub-normal	2	Incontinence, urine	2
" medium	7	Nausea and vomiting	29
" high	2	Mastoid tender and swelled	11
Facial œdema	1	Paralysis of limbs	18
" herpes	1	Pupils contracted	4
Nystagmus	1	" dilated	4
Neuralgia	1	Strabismus	4
Constipation	19	Diplopia	1
Delirium	19	Amaurosis	1
Maniacal	1	Facial paralysis	13
Unconsciousness	9	Amblyopia	1
Convulsions	21	Ptosis	1
Epilepsy	3	Paralysis of auditory nerve	1
Vertigo	13	Episthotonus	1
Coma	29		

I have also prepared a table showing symptoms that occur in *pure* cases of the intra-cranial presence of pus, *uncomplicated* by any lesion of the veins or sinuses. These symptoms do not occur in any other class of cases under consideration.

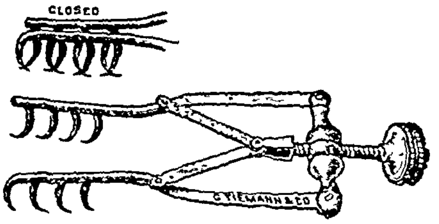
Deafness.
Temp. sub-normal.
Pulse sub-normal.
Maniacal.
Epilepsy.
Aphasia.
Insomnia.
Pupils contracted.
Pupils dilated.
Paralysis of auditory nerve.
Incontinence of urine.
Paralysis of limbs.
Facial œdema.
Nystagmus.
Neuralgia.
Constipation.
Amaurosis.
Ptosis.
Tinnitus aurium.

And I have also noticed those symptoms that have occurred in both forms of the disease, but have predominated in those cases where there was an intra-cranial presence of pus, outside of the veins and sinuses. These are as follows:

Coma.
Convulsions.
Unconsciousness.
Somnolence.
Stupor.
Nausea and vomiting.

We now turn to the subject of the treatment of these cases. There is but one resort for an intelligent surgeon, and that is to operate. The question simply is, when to do it and how to do it?

In a case of either acute or chronic otorrhœa with or without mastoid symptoms, where brain phenomena supervene, we should first give the patient the benefit of a doubt by freely opening the drum-head, both in its lower segment to secure good drainage, and in its upper posterior portion, where pus is prone to lodge. The patient should be kept quietly in bed, and the fountain douche, with very hot water should be allowed to run into the ear every hour during the day, and several times at night. Inflation should be used once or twice a day. A few days may be allowed to elapse—unless extra-dangerous symptoms occur—and if the patient is not then practically better, the mastoid process should be freely opened. As large an opening as possible should be secured. If the mastoid speculum devised by myself be used, the operation will be practically bloodless, and made with much greater facility and certainty.



I feel sure the mastoid should *always* be opened in such cases, before the skull is opened, as there is a very reasonable chance, that the mastoid antrum or cells, may be the focus of disease, and that this operation will suffice. The records that I have compiled show conclusively that in some of the cases, a much better and speedier result would have been obtained had this idea been adopted.

We may find within the process, for instance, caries or necrosis of the inner mastoid plate, or even a fistula, that may solve the whole problem, and render further operative interference unnecessary.

In case a softening of the internal mastoid plate is found, the diseased bone should be gently cut away, and if a perforation is easily made, it should be accomplished, the aperture enlarged, and the operation concluded in the same general way, as will be described later on.

If the perforation is not quite easily made, the procedures should be stopped at this juncture, and we should await developments.

If a fistula of the inner mastoid plate is found, it should be enlarged, and the operation concluded, as will be subsequently described.

In case the mastoid operation fails to relieve the patient, a perforation of the skull must be made. It may be deemed advisable to again direct our interference to the mastoid plate, in case a fistula has not been found, and if we found necrosis of the inner wall, but did not make a perforation at the first operation.

"Experience alone can tell whether after all it is best to seek for temporal abscesses, directly from the roof of the mastoid process. At all events, it offers the advantage of leaving the entrance of the wound *lower than the abscess*, so that the pus flows off easier, and the skull is not injured, sometimes very advantageous to the patient." (From Von Bergman.)

It is of course, evident that perforation of the inner mastoid plate, is only advisable in those cases where the indications point with reasonable certainty to an involvement of one of the middle lobes of the brain, especially the temporal.

An accurate diagnosis as to the seat of the abscess is of the utmost importance, and the leading points, so far as it is at present known, for such a diagnosis, may, I think, be gleaned from the preceding pages of this article. The two principal objective foci for operation, will be the temporal lobe and cerebellum.

In case we decide to perforate the skull, with the hope of locating an abscess in the temporal lobe, where is the best seat for operation?

This question may sometimes be answered after the proper flaps have been made, by the finding of an area of softened, necrosed bone, or possibly a fistula. In the event of such a discovery, the operation may be made at this point, the necrosed bone should be removed, and an opening effected, or the fistula should be enlarged.

But in case we are not guided, as before mentioned, the best place for opening is just above, and perhaps a little in front of, the bony meatus, directly over the superior line of the zygomatic arch, the temporal lobe at this point being about $1\frac{5}{8}$ inches wide.

This exposes the dura-mater near the tympanic roof, without wounding the middle meningeal artery, and is about the most dependent portion of the middle cerebral fossa, the squamous bone being exceedingly thin at this point, and easily perforated. The opening may be made with either the drill, chisel, dental engine, or trephine, and should be sufficiently enlarged, and the edges smoothed. Personally, I do not like the chisel, either for this operation or for opening the mastoid process. I do not feel that it is advantageous to an already inflamed process, or brain, to pound it. Salzer suggests that the concussion might cause the rupture of an abscess into the ventricle, or the sub-arachnoid space. I have operated upon 83 cases of mastoid abscess, with the drill, and have had uniformly smooth operations, never having struck the lateral sinus but once, and then experiencing no ill effects from its exposure.

Before the operation, the scalp, for a large area, around the field of operation should be shaved, and thoroughly scrubbed and cleansed antiseptically.

Chloroform should be used instead of ether, as it produces greater quietude, and less cerebral congestion and tension. The auricle should be dissected down, so as to thoroughly expose the position of the bony meatus. It may be held down by an assistant and suture, and will then be out of the way, and will not interfere with the steps of the operation.

A large circular flap should be made, with a broad base, sufficiently extensive to thoroughly expose the field of operation. This may be held back by an assistant and a suture. The parts may then be held apart by my mastoid speculum, which will also control the bleeding, if the blades are widely separated. If hæmorrhage however, should annoy the operator, Lanphear recommends hot (115° Fahr.) water to be applied to the parts, and this should be ready for use during the operation, and must be thoroughly antiseptic.

(*To be continued.*)

SELECTIONS.

EDUCATION AND RESEARCH.—Professor Virchow's recent rectorial address to the University of Berlin will appeal to a far wider audience than that great University, and has a weight deriving not only from the importance of the subject discussed, but also from the position and great endowments of its author, whose attainments as a pathologist are equalled by his wide philosophical culture and his rich experience of life.

After touching upon the value of such annual occasions, when we examine ourselves, sum up our gains, prove our methods, and glance into the future, the Rector went on to say that the vast changes in the sphere of learning during the last half century had amounted to a revolution. Our older methods have been found wanting and are largely broken down, and the position both of school and of university teaching must be conceived afresh. This no man can do from the universal point of view; no man is a "Träger alles Wissens"; we must, therefore, all contribute, each from our own standpoint.

The conflicts between students and authorities in Germany, deplorable as at one time they were, have happily ended in securing freedom of teaching and freedom of learning, teacher and scholar having each his own independence and responsibility. The student who comes up from school to university is tempted by this absence of restraint to self-indulgence or pleasure, but if by these seductions he wastes even the first term, he may find it impossible to recover the lost ground; and if at the end of his university career he has not reached an average place in his education, he will probably be a bungler for the rest of his life, as the opportunity for "freedom of learning" will probably never return.

Out of the practice of this "freedom of learning" comes delight in learning, and this will decide for him between the various kinds of learning; a university uses no compulsion, and unhappily of late years the influence of teachers can be but little upon individuals, but is exercised upon the students in the mass. It is said that there is thus some falling off in the forming of students. In medicine especially is this true, wherein a student comes strange to an oppressive fulness of new ideas and new subjects of study, and is soon disheartened if the groundwork has not been well laid at the beginning.

What is to be done, asks Virchow, under this overwhelming progress of knowledge, time remaining the same or even growing less, so that both teachers and scholars are overweighted? So large a question could not be fully dealt with in an address, but certain aspects of it were considered. In the first place, the Rector appealed to the higher schools to kindle the "love of learning" rather than stuff their scholars with much information of a positive and detailed kind. Moreover, he called upon them to send up scholars *competent for independent study*, young men able to pursue their own course of work, not leaning upon others, not needing special stimulants at the hands of their teachers.

In detail, of course, each faculty must indicate its own requirements, but if love of study and self-help be previously brought out, the development of the student will be continuous, "Every normal child loves learning," has joy in new objects and in new uses for its organs, special senses, and reason, and whatever the variety of inherited talent this disposition should increase with its years. Two dangers, however, beset it—the danger of crushing this love, as too often it is crushed, by unfit or dull methods of teaching, and the danger lest thirst for knowledge degenerate into mere desultory curosity. Against the latter tendency the historical method is the best preservative.

In the next place Virchow appealed to the higher schools to weigh well their duties in respect of the two classical languages which hitherto have enjoyed the "lion's share" of the curriculum. Latin is inherited by our grammar schools from the time when it served the precious purpose of welding all Western thinkers together; now "national tongues have come into their natural rights," and we have succeeded to and sanctioned a state of "Babylonian confusion of tongues." The welding function of Latin is therefore ended, and, on the other hand, the works of Latin writers are seen to be far inferior to those of the Greeks, who were the fecund sources of thought and form. "Homer, Aristotle, and Plato are in our day the masters of the nations." So by culture and custom Latin must recede, and its grammar, to which its methods have largely fallen, will not much longer discourage the youthful mind. Medicine indeed alone of all the faculties has an unbroken tradition of 2,000 years from the Greek, but even to it Hippocrates and Galen are no longer of use, and Greek is seen rather to have its place in the spheres of philosophy and poetry.

For modern teaching, mathematics, philosophy, and natural science are the prime methods—"the golden triad" upon which progress rests. From them we shall derive that large wisdom which the Ionian Greeks taught us to desire. In the schools, therefore, youths must be led to study the principles of astronomy and biology in their simpler aspects, for astronomy is the pattern of mathematics and physics, and in chemistry they must learn the art of experiment. Yet weight and measure are not all. How shall he, whether theologian, jurist, physician, or schoolmaster, consider psychology who has not learned the forms of thought? If philosophy cannot be taught in schools, they must teach "respect for philosophy." Finally, the Rector pointed out the farther difficulty that universities stand now in mid fight between the claims of the higher education on one side and of technical training on the other. Experience has not yet taught us to decide between these rival claims, and teachers vacillate. No compromise is as yet in sight.

It must be admitted that mere special training can be given without that larger development of the whole man at which universities aim. For such specialist studies technical schools and seminaries suffice. A university is not a mere aggregation of technical schools; it aims at an interpenetation of all faculties, at general conceptions. Unhappily, from the lack of preliminary training in the higher schools, university teachers have their time wasted in foundation work. Now, if a university is to hold its proper place, it must be not only an institute of learning, but also an institute of research, and the former cannot exist without the latter. University teachers should therefore have more time at their disposal than other teachers, and should not, because of deficiencies of the schools, have this time occupied in elementary instruction. The university must be an association of leading thinkers and investigators in free coöperation, and their students must come to them with a love of learning and with their faculties trained to the independent pursuit of it.

At this moment, when the establishment of a new and great university is under consideration, and when public school teaching is chaotic and unfruitful, we have felt it to be our duty, even at some length, to set forth these wise words of one of the leading thinkers of our profession.—*British Medical Journal.*

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, DECEMBER 17, 1892.

ON FORMS OF ALBUMINURIA YIELDING A FAVORABLE PROGNOSIS.

That certain forms of albuminuria may exist without disease of the kidneys, or, at least, without a primary affection of these organs, is a well established clinical observation; but the fact that, as a rule, such cases afford a favorable prognosis is not generally accepted. Without including unavoidable albuminuria, where the presence of blood or pus in the urine fully accounts for the existence of the albumen; nor febrile albuminuria, where the albumen is clearly the result of elevation of bodily temperature, or disturbance of circulation in the kidneys, we have remaining for consideration a well-marked group of cases in which albuminuria has its origin or immediate cause in some alteration, either transitory or more or less permanent, in the composition of the blood. FOTHERGILL, in his monograph on "Vaso-renal Change *versus* Bright's Disease," summed up the evidence in support of his favorite view that the presence of an excess of uric acid in the blood is the starting point of the arterio-capillary fibrosis, of which the cardiac hypertrophy, the increased arterial tension and the progressive degeneration of the kidneys with albuminuria characteristic of Bright's disease, are the natural sequences. The increase of uric acid and similar primitive excrementitious material, he attributed to a failure of the liver to sufficiently elaborate the nitrogenous material so as to convert it into the more soluble form of urea, since some of the lower animals (for instance, birds and snakes) discharge a urine consisting almost entirely of urates or of uric acid, he considered that this excess of uric acid in the human organism is an indication, on the part of the liver, of reversion to a lower type. Thus an overworked, especially a naturally inadequate, liver, being unable to perform all the duty imposed upon it in the way of converting excrementitious nitrogenous waste into urea, would readily revert to a more primitive type of organ and furnish uric acid instead of the more highly oxidized urea. The effect of such a failure on the part of the liver would be to give rise immediately to the condition of lithæmia, and this in turn to more or less frequent acute attacks of gout, either in its typical form, or in its more obscure manifestations in lesions of the nervous system, and of various individual organs. The kidneys of patients in whom this state of the blood has existed for any length of time are so commonly found to be the site of cirrhosis, that the small, contracted kidney is frequently called the "gouty kidney." Hypertrophy of the left ventricle of the heart, and atheromatous degeneration of the aortic valves, are likewise now considered as preëminently gouty in their origin; since they are found commonly associated with the other signs of this diathesis which have been already referred to.

More light has been thrown upon this subject recently by an observer whose previous contributions to the pathology of Bright's disease and his work in the field of clinical medicine and diagnosis, entitle him to speak with authority upon these mooted questions as to the origin of albuminuria. At the annual meeting of the Philadelphia Pathological Society last month, PROFESSOR J. M. DA COSTA delivered an address, taking for his theme "The Albuminuria and Bright's Disease of Uric Acid Formation and Oxaluria." He first insisted upon the fact that there is a distinct group of cases of the kind with albuminuria, the pathology of which is not clearly understood; but which, clinically, are easily separable from the classical forms of renal disorder. They are unlike in origin, pursue a different course, call for special treatment, and have, as a rule, a favorable prognosis.

The diagnosis of this form of albuminuria from the typical forms of Bright's disease, is not difficult. In the first place, the albumen, which is variable but never present in large proportion, is accompanied by casts only exceptionally, and these are of the epithelial variety, never fatty. The most marked characteristic, apart from the albuminuria, is the high specific gravity of the urine. In many cases this was the first symptom which excited attention; the urine is persistently 1025, 1030 or above. It is acid in reaction, and contains, in one class of cases, an excessive proportion of uric acid and urates; in another, there is marked oxaluria, or both forms may coexist. The principal symptoms are digestive disorders, flatulence, constipation, depression of spirits, and in fact the usual nervous and digestive symptoms of lithæmia. The absence of dropsy is noteworthy, as well as the entire absence of eye symptoms. It is also to be observed that in the class of cases under consideration, the arteries are not rigid, the pulse is not indicative of high tension, and the heart is not hypertrophied, although its action may be accelerated and the pulse may be intermittent. In the cases with oxaluria, there is to be noticed a greater amount of nervous depression and gloominess, but the same amount of dyspepsia as those in which there is excessive uric acid excretion. A tendency to an afternoon rise of temperature was frequently observed by Da Costa, in these patients.

The persistent high specific gravity of the urine, the absence of eye-disorder, of cardiac hypertrophy, and of high arterial tension, afford diagnostic data, distinguishing these cases from those of contracted kidney, which is the form of Bright's disease most likely to be mistaken for this albuminuria of uric acid formation and oxaluria. At the same time the lecturer was of the opinion that this condition might in the course of time, in exceptional cases, develop this form of Bright's disease of the kidneys, and he referred to such a case occurring in his practice.

It is a curious fact that nearly all the cases of this form of albuminuria occur in the male sex; the lecturer had met with only one case occurring in a woman.

The relation which this form of albuminuria may bear to cyclical albuminuria, the albuminuria of adolescents, and similar intermittent forms of albuminuria, is a question of immediate interest, which at once suggests itself to the mind of the reader. Prof. Da Costa considers the relation a very close one; especially since upon reviewing his notes of former cases of albuminuria of adolescents, which, by the way, occurs chiefly in boys, he was struck with the uniformly high specific gravity of the urine, the significance of which was hitherto not understood. The coincidence of the presence of an excess of urates and of oxalates in the urine was also noticed in going over the literature of the subject. The fact that boys are very active in their habits and fond of exercise must be taken into account, since Grainger Stewart stated that, in a company of soldiers after prolonged marching, it was found that a large proportion had albumen in their urine, an observation which has been since confirmed by others. The lecturer was inclined not to attribute the albuminuria directly to the effects of the exercise, but indirectly to the increased tissue change and the accumulation of excrementitious material in the blood resulting from the muscular exercise, thus producing a temporary lithæmia. He also was of the opinion that a great many cases of cyclical albuminuria, are really instances of this same lithæmic albuminuria and that they are likewise produced by increased excretion of tissue-waste.

The prognosis is good; the patients generally get entirely well. This is of great importance from the standpoint of the examiner for life-insurance since these cases are often rejected on the ground that they are victims of Bright's disease. He gave several instances in which the patients first learned of the existence of albuminuria through applying for life-insurance; and after being rejected they came for treatment; subsequently, they entirely recovered their health and the urine became normal.

The subject of treatment may be disposed of in a few words. In the first place, it is a great relief to the patient to be assured that he has albuminuria but not Bright's disease and that by regulating his habits of work and medical treatment he will get entirely over it. Dietetic regulation is of first importance. Da Costa does not insist strictly upon a milk diet, but milk as a food should occupy a prominent place. As long as the patient is able to take daily exercise, meat in moderation is allowed. Green vegetables and bread are permitted, but sugar, butter and starches generally are restricted or entirely forbidden for the time. Change of residence is often beneficial; several patients returned cured after a visit to Europe. As regards the special remedies to be used, he found laxatives of great service; indeed, good results usually follow the administration of the old fashioned blue pill at night and a saline the next morning. The activity of the kidneys should be maintained by citrate or acetate of potash, or similar drugs, and mineral waters used freely so as to flush out the tubules. It is of importance that exercise should be systematically taken, though not to excess. Inhalation of oxygen had not afforded decided results in his hands, but might prove of some service. Recurrence of the symptoms calls for repetition of this course of treatment.

The paper of which we have given the principal points will appear very shortly in full in the *American Journal of the Medical Sciences*. We congratulate the Pathological Society of Philadelphia, which in fact years ago was founded by Professor Da Costa, upon securing this valuable contribution to its annual volume of transactions.

APPENDICITIS IN FRANCE AND IN AMERICA.

From the discussion regarding appendicitis by the Paris Surgical Society (Bull. et mém. de la Soc. de Chir. de Paris, T. xviii), it is evident that unanimity of opinion upon some points as to treatment is not yet established in France, and that the French are somewhat behind the progress of American surgeons. The discussion as brought out in the society includes the etiology and pathology, the expectant opium treatment and early and late operations upon the inflamed vermiform, and is based upon the histories of cases presented and the results of operations performed. The adherents of the opium treatment (Berger, Moty, Marchant) thought that it was most advisable because they had obtained good results from its use even in cases where suppuration was highly suspected, and because recurrence of an attack is not always avoided by an operation. All are agreed that the indications for operation are positive when there is a large abscess that threatens to rupture into the peritoneal cavity, or when peritonitis has already commenced. The indications for an early operation are only relative and are dependent upon the presence of a positive swelling (RECLUS, SCHMIT). A swelling it is thought always indicates suppuration, even though the general symptoms have improved or the swelling decreased somewhat in size. Decision is not to be made until the swelling is positive, and then the indications would simply be those of an abscess.

As additional reasons for operation it was shown that the recoveries attributed to opium are fallacies, as recurrence is frequent and the cases usually come to operation at some later time; and also that the danger of an operation and of possible hernia is very slight. The earliest operations, where the indications are based upon symptoms alone, were not discussed and do not as yet seem to have been strongly considered by the French surgeons.

In this country, the opium treatment, although it is mentioned in the most recent text-book of American surgery, is hardly thought of by the practical surgeon. Operative indications are positive when there is a swelling and relative when based upon symptoms. The difference is evident and would seem to mean that either some men are still behind or that some are beyond the limits of rational surgery. There are American surgeons who are even more conservative than the French, who will defer operation until there are all the signs of an abscess or even until they see the pus in an exploring needle. These men are certainly behind the limits of rationality. The work of TREVES, MCBURNEY, SENN and others have placed appendicitis operations, either during or after an attack, upon a sound basis, and there is no need of waiting after the diagnosis is made. Among most advanced surgeons the position of appendicitis treatment is nearing the level of strangulated hernia; any involvement at all, either by symptom or sign, is a sufficient reason for operation. As was recently the case, a diagnosis was made three hours after the first symptoms and an operation performed within four hours, with the result of finding a perforation and saving the patient's life (VAN HOOK). This is certainly indicative of the highest treatment for appendicitis. The unfavorable prognosis because of resulting adhesions and *fistulæ* and the longer duration of the sickness, where interference is postponed under conservative treatment, are so important that resistance to early operations can no longer be maintained. America may also claim precedence, besides advocating the early operation, in that WILLARD PARKER of New York was the first to recognize appendicitis as an operable disease. The French surgeons look upon tuberculosis as an important etiology, and even in cases without tuberculosis in other parts of the body. As to methods, their discussion does not offer any new points.

REGENERATION OF MUSCLE.

RUDOLPH VOLKMANN has recently made an extensive study of the processes that result in regeneration of striated muscular tissue as shown in the skeletal muscles after typhoid fever, after the influence of very low temperature, in trichiniasis, and after injuries, actual and experimental. Among the results of his studies may be mentioned that in striped muscle the regenerative changes commence in the nuclei of old fibres with which the new elements may, or may not, remain connected. In the first instance the process corresponds to the formation of buds, as described by NEUMANN, while the development of new elements without direct connection with the pre-existing resembles the embryonal type of muscle growth. In both forms the proliferation of muscle nuclei and the growth of protoplasm around them form the beginning of regeneration and in both forms, which may go on side by side, the protoplasm early shows a fine fibrillar striation. A formation of new muscular fibres by means of longitudinal splitting of the old, was not observed by VOLKMANN. Muscular tissue is regenerated after the embryonal type in such lesions as affect the contractile substance only or principally; practically this means after the coagulation necrosis in typhoid fever and after exposures to low temperature. After solutions of continuity affecting sarcolemma and connective tissue the regeneration occurs by means of budding principally; the budding is usually terminal. *i. e.*, it occurs at the ends of the severed fibres, where nuclear multiplication by the direct method essentially takes place and a nucleated mass of protoplasm is formed, which grows rapidly in length in the same direction as the old fibres at the junction with which it becomes fibrillated. Such budding was observed to commence about eight days after the injury to the muscle and to continue for a variable length of time up to six or eight weeks. In regard to the ultimate result of the reparative activity in damaged muscle it was found that it was only sufficient to restore continuity in very minute wounds which might heal with pure regenerated muscular tissue. All wounds of any size heal by means of connective tissue which may become muscularized for one to two millimetres from each wound margin. Transplanted muscular tissue dies very soon, is absorbed and replaced by a scar each end of which is muscularized for a very short distance. In trichiniasis VOLKMANN could not observe any evidences of muscular regeneration. In typhoid fever degeneration and after exposure to cold of limited areas the regeneration was found sufficient to restore the affected muscles to their normal condition. In these cases the process of regeneration follows the embryonal type, as already stated, and the nuclei of the degenerated fibres multiply by the direct method and new cells are formed which are known as muscle cells and which absorb the waxy, dead remnants and give rise to new fibres by growth in length, so that each cell forms one fibre or, by coalescing, several muscle cells form one fibre. Scars in muscle develop after the degenerative changes of typhoid fever only when hæmorrhage or other extensive lesion has occurred. The process of regeneration in the striated muscles after typhoid fever is so pure and undisturbed that no better object for the study of these interesting phenomena than typhoid musculature can be found.

DRUGGIST AND PHYSICIAN.

The fact that druggist and physician are not working as harmoniously as of old is evidenced by the growing tendency to examine and analyze their true relations, and by the fact now being made clearly apparent, that a large body of medical men are in a considerable measure dispensing their own drugs.

There can be no doubt that the druggist is a great source of comfort to the physician, and that when he devotes himself to the profession of pharmacy in the spirit of a scientific seeker after facts, he is laboring for the best interest of the physician and the patient and is deserving of support and encouragement at the hands of the medical profession as a whole.

But unfortunately for all concerned he has chosen to place pelf above honor in many instances, and by so doing has cast an odium upon his honorable profession and freed the physician from all general obligation by his piratical ventures in the domain of patent medicine, counter prescribing and other like abominations.

An interesting change has lately manifested itself in the conditions of his business and he bids fair to be driven into the field of legitimate pharmacy, because there is no longer a profit in the illegitimate branch which has until lately flourished so rankly in our midst.

Patent medicines, colognes, toilet articles of all kinds, even soda water fountains, are finding a place in the large department stores, and prices are being cut to a degree which makes the business unprofitable to the purchaser of small consignments.

And while thus assailed upon the one side our druggist finds danger upon the other in the threatened desertion of his disaffected allies the doctors, who recognize in the new preparations a means of relief from a dependence which has in many cases proven most irksome.

Independence should be the watchword of our profession. The moment we lose or even relax our hold upon it we lack the right to claim especial consideration at the hands of our fellows.

Our object and aim is ever to secure for those under our care the greatest amount of benefit, and to that end we are to devote our own best energies and sacrifice personal comfort and often health or life itself, in our effort to maintain our profession upon that high plane which its intrinsic nobility merits.

We welcome all discussions looking to better conditions of work and hope that the near future may show us increase of scientific therapeutics and pharmacy, a deeper sense of individual responsibility and absolute professional independence.

The Quack Question as Handled by the City Council of Mansfield, O.—At the meeting of the Council of the city of Mansfield, Ohio, on Nov. 29, 1892, an ordinance was passed by a two thirds majority, which prevents any quacks or itinerant venders of medicine, "toothpullers" or other imposters practicing their nefarious schemes in that city without first getting a permit from the Health Officer, who, by the ordinance, is required to be a regular physician. The ordinance also requires these quacks to display a diploma from some respectable college before the Health Officer can give them the necessary certificate entitling them to a license at all. On the presentation of said certificate to the Mayor, they can receive a license for which they must pay not less than $25, nor more than $50 a day, and are also subject to a fine of not less than $25, nor more than $50, for each and every offense for the violation of this ordinance.

The law goes into effect immediately after its publication and covers physicians, mid-wives, pharmacists and dentists. If every City Council throughout the State of Ohio would follow the example set by the Council of Mansfield, they would take a grand step in the direction of getting rid of quacks and imposters which infest all our large cities. This plan has been tried in Kentucky, and so far has proved to be of great advantage in getting rid of these leeches, and should be followed by all the States that have no special laws or that cannot get special legislation to remedy this great evil.

NECROLOGY.

Dr. Wm. H. Geddings.

Dr. Wm. H. Geddings, of Aiken, died at Bethlehem, N. H., after a short illness on August 27. Dr. Geddings was the youngest son of the late Dr. Eli Geddings, of Charleston, S. C., and a brother of the late Dr. Frederick Geddings, of the same city, and Dr. Edward Geddings, of Augusta, Ga. Of a family of distinguished physicians, he was himself one of the brightest ornaments of his profession in the United States.

Dr. Geddings was born in Charleston, S. C., on the 23d day of April, 1838.

He first studied medicine at the Medical College of the State of South Carolina, at Charleston, and afterwards prosecuted his studies in the universities of Vienna, Berlin, Prague and Paris.

At the commencement of the war between the States' Dr. Geddings entered the Confederate army in the line of his profession, and shortly afterward rose to the position of Chief Medical Purveyor of the army of Northern Virginia, which high office he filled with distinction until the close of the war. He then settled in New York City and commenced the practice of his profession, but the health of Mrs. Geddings becoming impaired by the Northern climate Dr. Geddings on that account, moved South to Aiken in 1869, where he has ever since been continuously engaged in active practice; but for the past twelve years or more he has also engaged in a summer practice at Bethlehem, N. H., returning each fall to Aiken, the place he loved, where he was highly esteemed and enjoyed a lucrative practice, especially among the large number of visitors who were suffering with pulmonary diseases.

Dr. Geddings was a learned and strong man and a great physician. It was not only as a successful practitioner that Dr. Geddings became noted. He also attained a national reputation for his learning and as a distinguished writer on medical and scientific subjects. His writings are numerous, and he contributed freely to the medical journals, especially on climatology and the diseases of the respiratory organs. He also contributed many articles on Dermatology, having been at one time a pupil of the great Hebra. The latest of these was "A Contribution to the History of Leprosy on the Eastern Coast of the United States," which excited much interest among Dermatologists. He prepared the article "Aiken" in Wood's "Reference Handbook of the Medical Sciences." Perhaps one of his best articles was that on "Bronchial Asthma," prepared for "A System of Practical Medicine by American Authors," edited by Dr. Wm. Pepper. At the time of his death he was member of the following Societies: The American Medical Association, The South Carolina Medical Association, The Climatological Association, The Dermatological Association.

Dr. Geddings was married in July, 1866, to Miss Adele Getty, the daughter of A. Getty, Esq., of Philadelphia, who was a most devoted and tender companion, and is left to mourn his untimely end.

Graham N. Fitch, M.D.

Dr. Fitch, died at Logansport, Indiana, Nov. 28, 1892, aged 84 years. Dr. Fitch was one of the most notable men of Indiana, born in LeRoy, New York. His grandfather was a soldier in the Revolutionary War, and his father in the war of 1812. The subject of this sketch was educated at Middlebury, and at Geneva College, completing his medical studies at the College of Physicians and Surgeons, New York. He began the practice of his profession in his native town in 1832. In July, 1834, he located in Logansport, Ind.

Dr. Fitch was a member of the Indiana Legislature in the sessions of 1836 and 1837, and 1839 and 1840. He three times served as presidential elector. In 1844 he was appointed to a professorship in Rush Medical College at Chicago. From 1848 to 1852 he was a Representative to Congress from his district. From 1856 to 1861 he was United States Sentor. While in Congress he saw the gathering sectional cloud, and pointedly warned the South of the fatal consequences to them of the war they seemed to desire.

In the Presidential election of 1860 Senator Fitch advocated the election of John C. Breckenbridge, of Kentucky, who was the candidate of the south. This action was misconstrued and he was heralded as a rebel sympathizer. His action was explained by his adherence to Democracy and his unwillingness to support Stephen A. Douglas, the northern Democratic candidate for personal reasons. There had been a difficulty between the two in the Senate, resulting in the sending of a challenge by Douglas to Fitch. The latter promptly accepted but as his marksmanship was unerring, friends of Douglas interferred, and while the duel never came off the feeling continued. Thus the support of Breckinridge and the misconstruction it led to. When the war broke out Senator Fitch organized the 46th regiment, and assisted in filling two other regiments. With his regiment he was placed under General Buell's command at Louisville, Ky., later he joined General Pope, and was immediately put in charge of a brigade. He participated in the sieges of Fort Thompson and Island No. 10. After the fall of these posts he was detailed, with his brigade, to lay siege to Fort Pillow, in conjunction with the navy under Commodore Davis. The day following the fall of Fort Pillow, Colonel Fitch captured and garrisoned Memphis. A few days afterward he moved up White River, Arkansas, and captured, by assault, the fortifications at St. Charles. At the last place he took prisoner the wounded commander of the Confederate batteries, the unfortunate Col. Fry, of Cuban notoriety. Col. Fitch had two sharp engagements with the Confederates in Arkansas, in both of which he was victorious. An injury received in that State, by the fall of his horse while on a reconnoitering expedition, compelled him to leave the service before the expiration of the war. He was an ardent Democrat, but he never hesitated to dissent from his party when, in his judgment, its course was not for the best interests of the country. Many years ago he retired from all active participation in politics.

As a public officer he always fearlessly and faithfully performed every known duty. As a physician and surgeon few men have been more actively engaged or met with greater success, and he continued to practice his profession for the good of humanity until his last illness.

He was a member of the Medical Convention, which met in Philadelphia in May, 1850, for the purpose of revising the U. S. Pharmacopœia, as a delegate from Rush Medical College, Ill., and was appointed upon the Committee on Revision and Publication. He attended many of the meetings of the American Medical Association from an early date, among the last were those at Atlanta and Chicago. He occupied the chair of Professor of Principles and Practice of Surgery in the Medical College of Indiana, for four years and was Emeritus Professor at the time of his death.

Dr. Enoch Fithian, formerly of Bridgeton, New Jersey, died at his home in Greenwich, November 15. He was the oldest graduate of the medical department of the University of Pennsylvania, having been a member of the class of 1815. He continued in medical practice in Cumberland county for fifty years, or about thirty years ago. He was the first secretary of the county Medical Society, and afterwards became its presiding officer. After his retirement from active practice, Dr. Fithian gave much time to local historical subjects, and he has left behind him many pages of retrospective local interest. He was said to be the oldest living Free Mason in the United States, his tenure of membership having covered fully seventy-five years. At the last election Dr. Fithian, with assistance, went to the polls and cast his eightieth annual ballot. One day in May last he celebrated his centennial birthday, his birthyear having been 1792.

Dr. James R. Leaming, of New York City, died December 5, in his seventy-second year. He was a native of Groveland, New York, educated at Genesee, and graduated at the University Medical Department of the city of New York. This latter event took place in 1849, and in that same year young Dr. Leaming took up his permanent residence in the city last named. He early took an esteemed position in the profession, becoming especially valued as a consultant in pulmonary diseases. In 1867 he was appointed visiting physician to St. Luke's Hospital, and later became the consulting physician to that institution, and to the Tremont House of Rest for Consumptives, also Professor of Theory and Practice in the Woman's Medical College. He was prominent in the scientific deliberations of the Academy of Medicine, and a few other societies, but he was reluctant, from reasons pertaining to his health chiefly, to take office in the bodies to which he belonged and of which he was an honored fellow. His final illness was ascribed to pulmonary and cardiac complications, not the least painful of which was a fibroid phthisis, the very malady that had oftentimes occupied his thoughtful attention, and that was the topic of his discourse before the Academy in 1876. He joined the American Medical Association in 1880. Nearly all his writings have reference to thoracic diseases and their diagnosis.

BOOK REVIEWS.

A POCKET MEDICAL DICTIONARY, GIVING THE PRONUNCIATION AND DEFINITION OF ABOUT 12,000 OF THE PRINCIPAL WORDS USED IN MEDICINE AND THE COLLATERAL SCIENCES. By GEORGE M. GOULD, A.M., M.D., etc., etc. Philadelphia: P. Blakiston, Son & Co. 12mo. pp. 317.

This little book is modern in its make-up, and adapted to the use of students and writers. It contains many useful tables and information of interest to the physician and pharmacist.

MEDICAL MICROSCOPY. A GUIDE TO THE USE OF THE MICROSCOPE IN MEDICAL PRACTICE. By FRANK J. WETHERED, M.D. (London), Member of the Royal College of Physicians. With illustrations. Octavo, pp. 406. Philadelphia: P. Blakiston, Son & Co. 1892.

This book attempts to give an account of the microscope and the optical laws that govern it, (p. 30), the microtome and its construction (p. 10), and the various methods of hardening and decalcifying (p. 12), of imbedding (p. 9), cutting (p. 11), staining (p. 35), and many other technological methods. The antiquated methods recommended astonish one and give us little hope for better work in the future from those who use this book as a guide. It seems astonishing that at this time no better, simpler, or more practical recommendations can be made to the physician than those here set forth. The most valuable part of the work consists in the pages devoted to the microscopical examination of clinical material for diagnostic purposes. In this part of the work there are a few not very good illustrations, and a fair amount of well arranged instruction and advice. A chapter is devoted to bacteriology, and the stereotyped figures and methods are used. Not a very great future for the work can be predicted, but in the hands of a good teacher it would become a cheap ($2.50) and convenient handbook for a laboratory course in clinical diagnosis.

THE ESSENTIALS OF HISTOLOGY, DESCRIPTIVE AND PRACTICAL. FOR THE USE OF STUDENTS. By E. A. SCHAFER, F.R.S., etc. Third edition, revised and enlarged. Illustrated by more than 300 figures, many of which are new. Octavo, pp. 302. Philadelphia: Lea Brothers & Co. 1892.

This beautiful book from the Glasgow University press is a valuable addition to our literature on this subject. It unfortunately does not maintain all the good qualities of the Section on Histology of Quain's Anatomy, by the same author. It must, however, be looked upon as one of the most complete manuals for class-room instruction, which we have at the present time. The arrangement of the course is admirable, and it is well adapted to a systematic laboratory course, with a live teacher. The amount of illustrations makes it possible to use it as a work of reference in a small way. The histological methods recommended are not of the most simple and uniform character. We believe that it would be a great improvement to have more simple and yet full and useful technological methods recommended. This book savors too much of the "shorter course in" series, but it has as few of the faults of such condensations as could be expected.

MCARTHUR DIARY FOR 1893.—Any physician who has not received a copy will receive one, on application, without expense. Address McArthur Hypophosphite Co., Ansonia, Conn.

MISCELLANY.

PRELIMINARY ANNOUNCEMENT of the sixth annual meeting of the National Association of Railway Surgeons, embracing the United States of America, the Dominion of Canada, the Republic of Mexico, to be held at Omaha, Neb., the last Wednesday, Thursday and Friday of May, 1893.

General Subject: Injury of the Cord and Its Envelopes Without Fracture of the Spine. 1. History, by Dr. Geo. Ross, Chief Surgeon Richmond and Danville R. R., Richmond, Va.; 2. Anatomical Landmarks, by Dr. Jabez N. Jackson, Surgeon Wabash R. R., Kansas City, Mo.; 3. Physiology of the Spinal Cord, by Dr. A. P. Grinnell, Chief Surgeon Central Vermont R. R., Burlington, Vt.; 4. Experimental Research, by Dr. B. A. Watson, Surgeon Pennsylvania R. R., Jersey City, N. J.; 5. An Experimental Study of Spinal Myelitis and Meningitis, by Dr. George A. Baxter, Division Surgeon Chattanooga Southern R. R., Chattanooga, Tenn.; 6. The Clinical Aspects of Spinal Localization, by Dr. Nicholas Senn, Surgeon Chicago, St. Paul and Kansas City R. R., Chicago, Ill.; 7. Diagnosis from the Standpoint of the Neurologist, by Dr. C. H. Hughes, Consulting Surgeon Missouri Pacific R. R., St. Louis, Mo.; 8. Pathology and Pathological Anatomy, by Dr. Samuel C. Benedict, Surgeon Richmond and Danville R. R., Athens, Ga.; 9. Prognosis, by Dr. Samuel S. Thorn, Chief Surgeon Toledo, St. Louis and Kansas City R. R., Toledo, O.; 10. Treatment, by Dr. W. A. Outten, Chief Surgeon Missouri Pacific R. R., St. Louis, Mo.; 11. Medico-Legal Aspects, by Judge J. H. Collins, Chief Counsel Baltimore and Ohio R. R., west of the Ohio River, Columbus, O.; 12. Statistics of the Amount of Money paid by the Railroads of the United States, during the last Ten Years, for Alleged Injuries of the Spine, by Dr. F. K. Ainsworth, Surgeon Southern Pacific R. R., Los Angeles, Cal.; 13. Clinical Report—1. from a Medical Aspect—(*a*) Permanent Injuries—(*b*(Alleged Injuries; 2. From a Legal Aspect—(*a*) Settled with Suit—(*b*) Settled without Suit—(*c*) Miscellaneous, by Dr. Geo. Chaffee, Surgeon Long Island R. R. Brooklyn, N. Y.

C. W. BROCK, M.D., Pres., E. R. LEWIS, M.D. Sec.,
Richmond, Va. Kansas City, Mo.

OFFICIAL LIST OF CHANGES in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from December 3, 1892, to December 9, 1892.

By direction of the President, the retirement from active service on December 4, 1892, by operation of law, of Col. Anthony Hegar, Asst. Surgeon, under the provisions of the Act of Congress approved June 30, 1882, is announced, and he will proceed to his home.

Major John O. Skinner, Surgeon U. S. A., leave of absence granted on account of sickness, is extended six months on account of sickness.

Major J. C. G. Happersett, leave of absence on surgeon's certificate of disability granted in S. O. 178, Dept. Dak., November 18, 1892, is by Par. 6, S. O. 286, A. G. O., extended three months on surgeon's certificate of disability.

OFFICIAL LIST OF CHANGES in the Medical Corps of the U. S. Navy, for the Week Ending December 10, 1892.

Asst. Surgeon L. H. Stone, from the "Pinta" and ordered home, one month's leave.

Asst. Surgeon L. L. Young, from the "Mohican" and ordered to the "Pinta."

P. A. Surgeon H. N. T. Harris, from the "St. Louis" and wait orders to the "Bancroft."

P. A. Surgeon V. C. B. Means, from Naval Hospital, Norfolk, and to the "Saratoga."

P. A. Surgeon J. M. Steele, from the "Saratoga" and to the "St. Louis."

ORIGINAL ARTICLES.

THE RELATIONSHIP OF FOOD TO SCORBUTUS IN CHILDREN.

Read in the Section of Diseases of Children, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY E. F. BRUSH, M.D.,
OF MT. VERNON, N. Y.

The question of scurvy in infancy is, I think, one of the phases of children's diseases that has been lost sight of very largely in the study of pediatrics. There is no doubt but that the disease exists in infancy to a greater extent than we are aware, or should infer from medical literature. There can be little doubt when your attention is called to the fact, but that you will agree that many of the cases reported as rickets and marasmus, should be classified as scorbutus. Dr. Northrup, of New York, read a paper on scorbutus last September, in Washington, before the Pediatrics Society, and I think much good will come from this paper, which was a very interesting and instructive one, calling as it does the attention of pediatricians to the fact that such a disease occurs in infancy, and that it is characterized by very nearly the same pathological phenomena as is the disease in adult life. Now as this affection in the adult is well recognized, and the cause pretty well understood, I think it would not be amiss for me to call attention to some of the conditions in adult life that stand in a causative relation to the development of scurvy, and then we can see how prone to the affection the artificially fed infant of to-day must be. Every living creature on earth, or in the water thereof, subsists on matter that was once alive, and all food with the exception of a few condiments has been living, growing matter at one time. I think it can be safely affirmed that man is the only animal who not only kills his food, but makes it absolutely dead and sterile before he consumes it for his nourishment. The old adage, "that God sends the food, but the devil sends the cook," means more than has been credited to the saying. It has always been supposed that the unpalatable preparation of food was the devilish cooks' work, but I believe the cook whom the devil has sent to mislead us is the chemist. With his retort and his balances, with his reagents and his surmises, he has led us to believe that God has failed to do his work properly by uniting the nutritive materials in a living form, and possessed with a vitality that the chemist knows nothing about. He has taken up a deal too much room, and made things altogether too complicated. The chemist would have us believe that man needs for his nourishment only so much nitrogenized and so much non-nitrogenized matter; that the material with which the Creator has united these, and the vitality with which he has endowed it, is totally unnecessary. According to the advanced ideas of the chemist, a little jar of Liebig's extract of beef is far better than ten pounds of meat in the form we find it in nature. Milk that has been skimmed, dried and powdered, and mixed with a little cocoa butter, is far better than fresh milk from the laboratory of nature as the Great Giver has allowed us to procure it. I remember seeing it stated in some standard work, that when the chemist had reached his goal, armies would be able to carry in a small vial all the nourishment that was needed for their support for several days, instead of the weighty load of bread and meat which they are now obliged to carry.

I tell you gentlemen, the chemist has tried to be too smart, and we have been duped by him in many instances. Every living creature requires for his proper nourishment some raw living food. Every young living creature needs living food. The mammalia all take it direct from the living fountain, and young feathered tribes are supplied by their parents with living creatures for food. Even the young fishes consume the living animalculæ, and man seems to be the only one of God's creatures who thinks he knows better. The artificially fed infant gets his food from the knowing chemist, or must according to the prevailing fashion, have all the life sterilized out of it, if he gets any as nature supplies it without the intervention of the chemist. I am positive that there is more in organism, and the vitality that holds it together, than is dreamed of in our advanced chemical knowledge.

We know that the sea-faring man, the soldier, the peasant of a famine stricken district, are all subject to scurvy when they are deprived of fresh living food, and any growing vegetable, animal matter or other material not dead, will cure the disease. Milk retains its anti-scorbutic qualities for a few hours, so does meat after the animal is subjected to what we call killing. I suppose the muscular response to electric excitability will indicate the point at which meat retains its vitality after the animal has been killed, and I think it is a well known fact that vitality is the anti-scorbutic quality of a food. Now if the absence of this quality for any given time from the nutritive material of an individual, produces such dire results as scurvy, it must follow that this principle is a necessary condition for proper nourishment, and the chemist's idea of proximate principles being the only necessity for nutriment, must be a fallacy. Of course neither the medical man nor the chemist knows what vitality is, but it is with us everywhere, and by reason of its possession, we ourselves live and move, and have our being, and every article of food we consume was gathered together, and formed into nutritive food for us by the living and growing quality of vitality. Is it unreasonable to suppose then, we can get from this quality some sort of force that is necessary for our well being, and are we not depriving ourselves of some absolute necessity, when we eliminate every vestige of vitality from our daily bread? Since I have been possessed with this idea, I have observed several cases of simple dyspepsia recover completely by the use of live raw food. A few months ago, a patient came to me complaining of violent attacks of vertigo and temporary blindness. He had been losing flesh and strength for several months. I examined his urine, and found it to contain about 15 per cent. of albumen. He was directed to take nothing but living raw food—that is, milk not over four hours old, eggs laid but a few hours, raw oysters, raw clams, lettuce and other greens with no dressing, meat within a few hours after it was killed, eaten raw, apples, oranges and other raw fruits. No medicine except three drops of the tincture of nux vomica in water before meals as a placebo. At the end of fifty days the albumen had entirely disappeared. He had but few attacks of vertigo after he had the exclusive diet, and the attacks of temporary blindness never returned, and now after five months, he is in a better state of physical health than he had been before for years.

Now this one case proves very little, but it at least indicates that the diet must have had some influence in the man's recovery. I do not affirm that albuminuria always arises from the same cause, neither do I think any will affirm that defective nutrition is not one of the prominent etiological factors in Bright's disease, and if I am right in my deductions, one of the defects in our materia alimenteria is the absence of vitality; and if this is true regarding the adult, how much more must it be so with the luckless infant deprived of the normal living fountain which nature designed for its proper nutrition. I am firmly convinced that not only scorbutus and other serious affections arise from the absence of living food in the infant, but many of the weakly non-resisting babes succumb to disease, or live with more or less suffering, because of the absence of vitalized food.

One of the defects of the finite mind is its limit to be able to only harbor one idea at a time, and so when one man discovers a truth, he straightway imagines that he has solved all the mysteries of the science relating to the subject to which the discovered truth relates. I am willing to acknowledge that the vitality of a food is not its only requirement, but I am thoroughly convinced that it is one of the very important necessities to perfect nutrition. There can be little doubt that many children live who have been so improperly nourished (although fat) that life is more or less of a burden. A great deal of this may be due to their progenitors, their surroundings, and many other conditions, but some suffer by reason of improper food, and the method of its administration.

The French nation have as an executive officer in their scheme of government, a medical Health Officer. He has lately discovered that the death-rate in infants is so alarmingly large, that there is great danger of depeopling the nation, therefore he has issued an edict forbidding the use of the long tube nursing bottle in feeding infants, and I suppose he imagines that by this wise (?) law he will repeople France. If the death-rate could only be lowered by so simple an edict, our occupation would be gone; but we know that there are many other conditions, graver, more important and serious, than simply the form of a nursing bottle. There are very many things for us to find out before we know it all, but one fact I feel sure of, that the constant use of dead food with an infant is wrong. There is no greater field for the pediatrician, than the study of infant feeding. We must exclude from our councils, absolutely, the patent baby food manufacturer, and study how we can get a full supply of fresh, raw, living food to the unlucky infant who has to submit to an artificial diet, and then from the knowledge we are now in possession of, we will know that we are guarding the young, at least, from the danger of scurvy, and perhaps greater evils.

ACUTE MENINGITIS, WITH SPECIAL REFERENCE TO ITS TREATMENT.

Read in the Section of Diseases of Children, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY GEORGE N. HIGHLEY, M.D.,
OF CONSHOHOCKEN, PA.

The differentiation of diseases of the membranes of the brain has been a slow and difficult process. At one time all were regarded as varieties of hydrocephalus; later as forms of tubercular inflammation; and there is much diversity of opinion among modern writers and investigators. But our present knowledge of these affections must still be more or less speculative. This is particularly true of their etiology.

Of simple acute meningitis we know nothing definite as to its cause; its early diagnosis is difficult, and its usual treatment very disappointing. Indeed, so fatal is the disease that physicians are apt to doubt their diagnosis in cases that recover.

The object of this paper is to urge the importance of early recognition and prompt active treatment in this by no means rare disease of childhood.

I will consider only primary simple, acute meningitis, apart from its existence in connection with any preëxisting trouble, for in the latter case if the antecedent affection be of little consequence, it need not be considered in the treatment; and if on the other hand it be serious and grave in character, its management, like the treatment of tubercular meningitis, brings up a larger question than is contemplated in the scope of this paper.

What is acute meningitis?

It may be defined as an inflammation of one or more of the membranes covering the brain. In the simple, not tubercular, meningitis of childhood it is the pia mater, or inner membrane, which is usually affected. On this account Huguenin has called it leptomeningitis, a nomenclature which has been followed by other writers.

Inflammation has some common characters which are constantly present no matter where the disease may be situated. These are: hyperæmia with increased arterial tension, followed by exudation into the tissues of certain constituents of the blood; alteration of structure and of function; increased cellular activity. Accompanying these processes, and as a result of them, there is elevation of temperature, swelling and pain.

The course of inflammation is much modified by its location and the character of the affected part—thus when the disease affects connective tissue the tendency is to the formation of pus; when serous membranes are involved there is likely to be dropsical effusion; and in all affected organs and tissues in which there is a special function, that function is either suspended or greatly exaggerated and perverted. In inflammation of the pia mater we have therefore practically an inflammation of a serous membrane which produces disturbances of the complex cerebral functions and finally, if it continues, their complete cessation.

The cause of the disease in the majority of cases cannot be ascertained; it is indeed doubtful if it can be definitely determined in any case. Rigid investigation into the etiology of my own cases has been rather barren of results. Exposure to excessive heat (hot sun's rays), to sudden changes of temperature—in fact to all the conditions and influences which are supposed to produce inflammations in other parts of the body, may possibly produce the one in question.

The symptoms of acute meningitis are often not clearly defined in the early stage of the disease. It is not unusual to hear of cases being treated for "malaria" or for some other affection until the progress of the disease sets forth in unmistakable signs its true nature. Too often, then, has the golden opportunity passed for arresting it, and the physician finds it his painful duty to tell the friends of the little patient the true character of the affection and of its gloomy prognosis.

Is early recognition possible? Often it is true the physician does not see the case until considerable progress has been made, but if the disease can be detected during the stage of congestion, and before exudation has commenced, there are opportunities for treatment which if taken advantage of, may mitigate the force of the attack or completely arrest it. One of the earliest symptoms of the malady is vomiting—persistent vomiting which cannot be controlled by the usual remedies. It is present in nearly all cases and should excite suspicion whenever encountered. Preceding it, in a large number of cases, there is a disposition on the part of the child to be dull and languid, lying about much of the time; or on the other hand to be fretful and peevish, shrinking from the glare of strong light, restless at night, starting and crying out in its sleep. We have thus two varieties of symptoms, produced in the one case by hyperæmic pressure upon the cerebral centers, and in the other by irritation of those centers. In the latter class of cases, convulsions are not infrequently the first sign of the approaching disease. With that class, too, pain in the head is a prominent and persistent symptom. In all cases the pulse-rate is at first increased and then lessened, and again becomes rapid should the disease tend to a fatal issue. Pupils at first contracted; later widely dilated—temperature above normal, never high. Not to dwell in detail too long upon the symptoms of the disease, I beg to recall to your minds one more most valuable sign, and that is the character of the respiration. Slow shallow breathing with at intervals a long-drawn inspiration, is I think pathognomonic of the presence of the malady. It is difficult to observe the full phenomena of what is known as the Cheyne-Stokes respiration, but suspirations are almost invariably present.

These symptoms are present in the early stage of meningitis in varying proportions; some of them being prominent in one case and absent in another. In a few cases there are alternate periods of cerebral excitement and of lowered function of the brain centers. Should the inflammation go on unchecked, dropsical effusion soon begins in all cases, and the symptoms then are those of brain compression—pallid skin, enlarged veins, dilated pupils, slow pulse, drowsiness, deepening into coma, from which it is difficult to arouse the child. This condition may be changed to one of renewed irritation for a brief period, but continued coma is characteristic of this stage of the disease. It is doubtful if recovery has ever occurred after the period of dropsical effusion has arrived.

Is there any remedy for this most fatal malady? Can anything be done to stay the hand of this death-dealing disease? If we turn to our modern text books for an answer, we are deeply disappointed to find not a single remedy recommended that can be given with any assurance of success. Yet surely something ought to be done. To see a child, previously healthy and strong, suddenly stricken with a disease that must shortly destroy it, if there be no means of relief, is indeed a sad and serious thing. It certainly ought not to be allowed to go on without a strong effort being made to arrest it.

Fortunately there is a remedy which, if rightly used, will in the large majority of cases prove successful. I refer to venesection. Its use in the treatment of inflammation goes back to the dawn of medical history. From the earliest times it has been successfully employed in the management of this class of affections. Though at times temporarily thrown into disuse by gross abuse, its inherent value has kept it prominently in the foreground as a most potent means of treating this class of diseases. If we will but bear in mind the pathology of inflammations—a brief account of which I have endeavored to present to you—we can readily perceive the *rationale* of the remedy. In the first stage there is always congestion. Now there may perhaps be a congestion without inflammation; it is hard to conceive of an inflammation without congestion. The relation which they bear to each other is not yet definitely determined. It is probable that hyperæmia is merely a factor in the phenomenon of inflammation, and not its cause. Nevertheless, it is a most important factor, and the process cannot go on actively without it. Blood-letting blanches the congested tissues, relieves the pressure in the vessels and thus blocks the progress of the disease. No other remedy can do this so efficiently and with as little depressing effects as does this one.

The question at once comes to your minds, "Why is it that a remedy so long known and so often brought to the notice of the profession should not have received a more unanimous approval?" If the evidence of its value be so convincing to the few who have made use of it, why should not their testimony induce the many to at least give it a fair trial? Well, the majority of physicians are timid people. At least they are afraid of public opinion in general and their own patrons in particular. They do not like to incur the displeasure of the community in which they practice. Blood-letting seems to laymen a heroic measure and so they prefer to have "other things tried first." It does not appear to alter their opinion to know that after those "other things" have failed there is little use in trying anything else.

There is another reason why venesection has not been more generally adopted in the treatment of this class of affections; it is because most doctors follow the advice of a few men who have enjoyed the reputation of being leaders in the profession. These leading lights do not advise blood-letting; it is true they have nothing else which they can offer with any assurance that it will be successful—still they do not recommend venesection. And "better," says the average doctor, "better to lose more patients while pursuing the practice of the teachers than to risk losing a few while using an unsound plan of treatment." For in the first instance they can always assure the friends of the unfortunate that they have followed the practice of the most eminent men in the country and hence nothing more could have been done. The measure of value of a remedy is not by whom and by what class of men is it used, but what is the success which follows its use.

Until some other and better means shall be brought forth, venesection must stand as the most reliable and the most successful treatment of meningitis and all other inflammatory affections. When and how shall it be performed? It is manifestly the duty of the doctor to do it at his first visit if the presence of meningitis seems reasonably probable. It is certainly far better to bleed a patient unnecessarily than to omit doing so when there is urgent need of it. How much blood may be taken? That of course will depend upon the age and condition of the patient. The amount must always be sufficient to stop the engorgement of blood in the affected part. A child of four years can readily lose five or six ounces; more is sometimes demanded, less is often sufficient. In every case if, after a lapse of thirty-six or forty-eight hours, there is no improvement or the symptoms seem more pronounced, the operation should be repeated; or else local blood-letting by means of leeches or cups should be resorted to. The value of local abstraction of blood depends entirely upon the amount of blood taken. It is of course equivalent to venesection when a like quantity has been obtained, though this is generally difficult to accomplish.

Second in importance only to blood-letting, in the treatment of meningitis, is the application of cold water to the head by means of cloths wrung out of ice-water. When changed frequently and constantly applied they are, I think, greatly superior to ice bags and a most valuable aid to venesection in the management of this affection. When ice bags are used, two at least are necessary and a sufficient quantity of water should cover the ice, so that the cold may be more evenly distributed. One of the bags may be placed under the head and the other over the superior part.

Of medicines little need be said. Their value in controlling inflammation is more than doubtful. Theoretically they do so, but practical proof of their efficiency is wanting. To attempt to accomplish this result by the use of large doses of dangerous, depressing drugs, is surely a hazardous undertaking. The one indication for giving medicines is the relief of suffering. Headache, pains in the head, restlessness, etc., are best relieved by the bromides and small doses of morphia.

Let me now give you some practical proof of the value of the remedy. I will read you the history of three cases, which will be typical of many others, the first illustrating abstraction of blood by means of cups; the second by leeches; and the third by venesection and leeches.

Case 1.—Michael Feeley's child, aged two years, was taken ill October 25, 1888. Convulsion lasting nearly an hour. Saw the child shortly afterwards. It was still unconscious, pulse rapid, 120 to 125, pupils contracted, eyes turned upward with slight strabismus. After a few hours semi-consciousness returned. The little fellow lay languidly on his bed, his eyes half closed, but could easily be aroused. The next day (26th), there was no improvement. Pulse 120, respiration 28, temperature 100.5°. The peculiar breathing to which I have alluded was quite marked. At brief intervals there would be a long-drawn sigh (suspiration) followed by short incomplete respirations. The patient had vomited somewhat before being attacked with the convulsion. It occurred a few times on this and the following days. On the day of the convulsion I directed the use of cold water to the head and counter-irritation over pit of stomach. There being no improvement on the following day I applied cups over each temple, drawing about two ounces of blood. Ice bags were applied to base and fore part of cranium, they being partly filled with water in order to be more easily adapted to the shape of the skull. This was essentially the only treatment. After the cupping the child seemed somewhat better; and during the next two or three days a very gradual improvement took place. On the evening of the 29th symptoms of brain congestion again became marked. The cupping was repeated, a like quantity (two ounces) of blood being taken. Improvement once more set in though little change could be noticed for three or four days. The child was pale and became much emaciated. Gradual convalescence.

Case 2.—Andrew Fenelon's child, age two years. Was called to see it March 26, 1890. The mother told me that it had not been well for several days, the following symptoms being present: restlessness, peevishness, frequent attacks of vomiting, sensitiveness to strong light and no desire for food. When asleep it would often cry out or scream loudly, but would not rouse up when spoken to mildly. In addition to these symptoms, I found a rapid pulse, contracted pupils, pallid skin and irregular breathing. It was evident that I had a case of meningitis to deal with. I decided upon a good leeching as the best way to meet it. Three were applied, one to each temple and one back of left ear. The bleeding was allowed to continue for several hours, so that it is likely that at least three ounces of blood were removed. The vomiting now ceased, though the little one continued to be quite ill for one or two days; some improvement was then noticed. Child quieter, does not have any more screaming spells and takes a little food. On the fourth day after leeching it did not appear to be quite so well; lest urgent symptoms might again set in I directed the application of another leech, with the direction that its bleeding should be encouraged for some time. This was in the evening. The next morning the little patient was lying quiet, breathing easy and regular. Convalescence now continued slowly but without further interruption.

One more case illustrating the value of general blood-letting in this disease. To vary the evidence somewhat I will give you the history of a case that occurred in the practice of a neighboring physician —a man who through more than sixty years of active practice has had unparalleled success in the treatment of this class of affections.

The doctor was called to see Lizzie S., aged thirteen years, at midnight March 11, 1884. She had been suffering for about four hours with the most violent pain in the head, which made her scream out at short intervals. Vomiting occurred very often, pulse frequent and almost indistinct. Small doses of morphia with ten grs. bromide of potash were given every two hours. Next morning (12th), no improvement; patient vomited everything given her—even a small drink of water—face very pale, pulse rapid, could hardly be felt. Notwithstanding this apparently very weak circulation, the physician bled her at 6 P.M. eight ounces (8℥viij). At 9 P.M., three hours afterwards, he visited her again. There had been no more vomiting since the bleeding. Pulse still weak, face pallid. Ice-water cloths and ice bag had been applied to her head constantly since the beginning of the attack, and the patient repeatedly declared that they gave her much relief.

March 13, 8 A.M., pulse distinct at 80; face red, excessive pain in head, will not permit ice to be taken away from it even for a minute. At 2 P.M. these distressing symptoms still continued. Three large leeches were now applied to each temple. After being removed, the wounds were allowed to bleed for some time—until indeed she was as pale as death. The physician was now somewhat alarmed, though he felt that the blood-letting had not been carried too far, gave her *one-twenty-fourth gr. morphia and ten grs. bromide* pot., to be repeated every two hours until pain was relieved. She received two doses.

March 14, 9 A.M., patient had had some sleep; still complains of head, though more comfortable than on preceding day. Morphia and bromide to be continued until relieved. 6 P.M. applied blister over whole forehead to relieve pain, which has continued. Patient's general condition seems to be decidedly improved.

March 15, 9 A.M. Pain in forehead much relieved. Slept well, pulse 88, skin not so pale. Medicines were ordered *discontinued unless pain returned.*

March 15, 9 A.M. Patient still improves, has commenced to take food (she took none whatever during these days of distress). Gave oil to move bowels. Applications of ice still continued because patient will not permit their removal.

March 17. Took away ice bags and directed cold water cloths to be used instead. Convalescence continued slowly and patient did not require further active treatment. On the 23d she said she felt very well, and was able to sit up a few days later. She made a good recovery.

OUGHT INFANTS TO BE WASHED DIRECTLY AFTER BIRTH?

Read in the Section of Diseases of Children, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY FRANK S. PARSONS, M.D.,
OF NORTHAMPTON, MASS.
LECTURER ON DISEASES OF CHILDREN IN THE COLLEGE OF PHYSICIANS AND SURGEONS, BOSTON, MASS.

Doubtless most physicians find themselves confronted by this question nearly every week.

The dire results in some instances, where infants have been subjected to severe exposure to cold, during a prolonged process of this part of their toilet, would perhaps lead one to think a negative answer should be given. On the other hand, there are cases that have seemingly received the same treatment, and come out unscathed by any disease the etiology of which is credited to undue exposure to chilling influences.

There is, probably, no hygienic measure more tempting to a good nurse, than to arrange the toilet of the little one, making its body sweet and clean, as early as possible after birth.

If, as the custom is, we look to nature, as manifested in the lower animals, for a solution of this problem, we find that all the domestic, and so far as we are able to know the wild animals, wash their young directly after birth.

Of course there are many reasons why this fact, even though natural, can be no criterion to our treatment of the human race. The human mother cannot perform for her offspring such duties in the manner which the lower animals exhibit, nor would she be expected to were it a practical, or even fashionable thing to do. Then, too, the young of the lower animals being more thickly covered with short hairs or fur, the process with them is more one of drying the already wetted surface, than any particular desire for cleanliness. It is a natural instinct, or desire, on the part of the mother, to promote a healthy reaction of the skin of her offspring, who, in a wet condition, has suddenly been transferred from a higher temperature to one considerably lower.

With the human infant there is a different natural arrangement. A child has little, practically no, protecting hair. At birth it is suddenly ushered from an aqueous solution of nearly 100° Fahrenheit, to an aerial temperature from 20° to 30° colder. In other words, it has quickly been surrounded by a cold wave.

Then, if the infant is fortunate, it is received into some warmed flannel or woolen garment, and allowed to rest until the mother is amply cared for.

Now, while a baby has no constitutional environments for warmth and protection from exposing draughts, as has the animal, yet nature does provide an element of protection, seemingly for this emergency.

This is the sebaceous material consisting of fatty matter, epithelial cells, and other detritus found in greater or less quantity on the skin of the newborn child. This, if allowed, owing to the presence of the fatty matter, would naturally protect the infant from the chilling influences of reduced temperature to a considerable degree, and of itself become exfoliated about the time the umbilical cord separates.

However, the average nurse is imbued with the idea that, as soon as her other duties are over, the infant must be immediately washed, and turns her attention towards depriving it of this protecting element, by the application of soap and water.

Personally, I do not so much object to the washing of an infant directly after birth, as the manner in which it is commonly performed.

I trust I may be pardoned for occupying your time in rehearsing this part of the infant's toilet, as it is commonly done, and with which you all must be familiar, but I wish it contrasted with the method I shall hereafter recommend.

The baby, uncovered from head to foot, lies in the nurse's lap; she takes a soft sponge or rag, and with soap of a varying degree of alkalinity, and water of more or less warmth, washes small areas of the child at a time, and dries it with a towel or cloth of a greater or less degree of softness, until all stains and sebaceous matter are removed.

By the time this process is accomplished, and especially in cold months, the child may be seen shivering, and a bluish cast appearing over the exposed surface of its body.

Then the navel is hurriedly dressed, the infant attired in more or less suitable robes, and placed in bed with its mother to get warm.

Such is the treatment of a large per cent. of the children of to-day, and such are the cases that, *almost invariably*, develop catarrhal conditions varying in severity from simple snuffles to bronchopneumonia, with all its attending dangers.

I will not weary you with statistical references to cases of bronchitis, and other catarrhal affections, traceable to the first bath of infancy as a cause, as you all, doubtless, have had large experience in that line.

The question, then, is one of true infant hygiene. Should a newborn child be deprived of its natural protecting element? If so, what method should be employed to lessen the danger to the infant's health during the process?

If some little skirt with sleeves and hood could be contrived, made of some warm, unirritating material, such as canton flannel, in which the infant, after being quickly oiled with pure hog's lard, could be wrapped and allowed to remain four or five days, until it had become accustomed to the reduced temperature, and then properly washed, it would doubtless be a less exposing method of treatment.

This, however, will not suit the average mother, who wants her infant sweet and clean, and attired in all the paraphernalia of its wardrobe immediately after birth, so that it may be shown to the interested friends of the family.

This being an inevitable fact, it remains for us to devise some method of washing infants with the least exposure to cold, and for this *reason*, I have for some time suggested the following plan of treatment:

When there exists a large amount of sebaceous matter, ordinary soap and water will not remove it, so in these cases I direct the child to be previously anointed with pure hog's lard, this being the best solvent of the white sebum.

Then the child is quickly returned to the temperature from which it originally came by immersing it, to its neck, in a tub of water, the temperature of which is 103° Fahrenheit, or thereabouts.

Then the child, supported on the arm of the nurse, is with her other hand, or by the aid of an assistant, washed underneath the surface of the water, using only a soft linen rag or old handkerchief, the hem of which has been removed, and the best Castile soap.

Although not absolutely necessary, it is better, if possible, to have a second tub of water, equal in temperature to the first, in which the child may be rinsed.

This being accomplished, which should not have occupied more than five or six minutes, the child is quickly placed in a warmed absorbing blanket, and with the hand on the outside of the garment thoroughly but gently rubbed.

Afterwards the baby should be removed and rolled in a second warm and dry blanket, and allowed to remain a couple of hours, after which it may be dressed in garments suitable for comfort and protection.

I have never seen an infant, who has been treated in this manner, contract catarrhal troubles from an early bath, or have aught but healthy looking skins.

Greater care should be employed with children of unhealthy parentage, not only in the manner of bathing, but also other hygienic surroundings, and I firmly believe we can, by a little judicious early management, prevent a large per cent. of infant mortality.

ECZEMA INFANTILE.

Read before the Section of Diseases of Children, at the forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY B. MERRILL RICKETTS, M.D.,
OF CINCINNATI, O.

I believe that the subject "Eczema Infantile" will be of greater interest to this Section than any of the cutaneous diseases met during the first five years of childhood. It is a very common disease and one for which the general practitioner is frequently consulted. Not, however, until many of the numerous household remedies have proven themselves of no avail.

I do not care, on this occasion, to discuss the pathology or the cause from a bacteriological stand point. Neither do I care to report any special case or class of cases; only to speak of the eczema of childhood and its treatment, that we may discuss the management which has been the simplest, most easily applied with the best results, thus far obtained by the author. There is not any skin disease that is so aggravating to childhood. There are none more unsightly. Usually both the head and face are involved. There are a few, where the disease is pretty generally distributed over the entire body and extremities.

When this is so, the child presents a most pitiful spectacle. The itching and discomfort occasioned by this condition are very aggravating and are sometimes accompanied by the most severe convulsive movements. There is *nothing that appeals* to a man's sympathy so much as one of these unfortunate conditions. I have seen those in charge of these unfortunate children, utterly oblivious to the suffering that the child endures.

The causes seem many, but to my mind there is none so common as that of the excessive use of soap and water.

My experience has been that about 95 per cent. of these cases are due to this cause. The disease is not a respecter of persons, as it attacks the high and the low, the rich and the poor, and above all, the white skin races. The number of cases of this disease found among the dark skin races is proportionately very small. This perhaps, may be accounted for from the simple reason that the white skin is more delicate and easily soiled; hence the use of numerous cosmetics, which are so useless and injurious, and which are so extensively used. A clean faced child is the pride of every mother. She is lavish in the use of anything that will keep her child's face clean, usually the remedy that will remove the dirt the quickest. She uses these remedies more frequently with the thin, delicate skin of the child, than she does on the skin of her own face. The sebaceous glands should not exist if this law of extreme cleanliness holds good.

Nature is not responsible for children being reared in dirty atmospheres. These glands are for a purpose, namely to keep the skin constantly anointed with a fluid which protects the epithelium from becoming dry and fissured. That portion of the body which constantly should be anointed, is the one which is necessarily exposed to the wind, the rain, rays of the sun and dusts of various character, namely: the face and hands, which are forever exposed.

As the slime protects the epithelial structures of fish and mollusks, so does the sebaceous matter protect the cuticle of man. Birds anoint their feathers that they may be kept soft and pliable. Animals covered with hair, are likewise anointed by these glands, even the hairs themselves being supplied by oily secretion. The skin of the Mexican dog is rough, scaly and disagreeable to the touch. Not so with that of the hairy canine; his is oily and being so, enables him to endure more exposures to either the sun or rain, than his tropical ally. If we would but reflect, the cause of the disease, as a rule, could easily be determined, because having once been determined, the remedy is soon to be found. *Not until* mothers receive a certain degree of education in sanitary matters, can we expect a lessening in the number of these cases. At times the cause seems to be due to some nervous condition, while at other times there is indication that it is wholly local. The vesicular form, which is the most common, especially in infants, is obstinate and very trying to both the mother and child. After the disease *has manifested itself*, the child will begin to be irritable, restless, have loss of weight and a depressed appearance in general. It may have diarrhœa or it may be constipated, or they may alternate each other. The skin is reddened in places, resembling erysipelas, with a laceration here and there, showing where the nails of the child have been brought into requisition to relieve the intense itching. Crusts may extend over the face, head and shoulders or the entire body. The temperature is usually from one-half to a degree above normal. The hair is matted together with a pustule here and there over the affected area. There are many times deep and extensive fissures, especially about the ears, nose and lips, these of themselves causing much pain and discomfort.

If the hands are involved, it is usually the backs and between the fingers that the disease is most extensive. My experience has been that the disease is more frequent during the summer months. Having satisfied myself that the use of soap and water is the cause of this disease, at least in a very large proportion, I have for several years been treating it from this stand point.

The management that I have adopted is as follows: The mother is prohibited from applying water in any form, especially soap and water. A solution of olive oil and carbolic acid in the proportion of one to fifty is applied several times during the day to the affected areas, as often as the child seems to suffer from the itching. She is instructed to use the oil lavishly and to wash the child's skin with it as though it were water. This can be easily done, removing all of the dirt, leaving the skin perfectly clean, if a silk handkerchief or old linen fabric be used. The use of tea or coffee and all stimulants is forbidden. Also all kinds of food that should not be given to children at this age.

The child is allowed to be in the sun and enjoy the out-door exercise, even though its skin should become dirty. The olive oil and carbolic acid will prevent itching, so that the child will not lacerate the skin by scratching. In this way the injured parts are allowed to become healed, while the oil softens the crusts and keeps them from being reformed. $\frac{1}{20}$ grain of calomel is given every two hours; this I usually continue for one or two months, varying in frequency as occasion may require. If, after the third or fourth day, the child does not improve rapidly, I use salicylic acid in the form of an ointment, 10 grs. to the ounce. This is applied frequently to to the diseased parts, and is I think, one of the most satifactory applications that can be made. I believe that I have used about all of the preparations that have been mentioned for this disease, but I have found none that gives greater satisfaction.

Usually I do not see such patients more than three or four times, as the recovery will be as rapid without as with me, if the mother is faithful in carrying out all instructions. I do not know in what way the calomel acts; I give it whether there is constipation or diarrhœa. Sometimes there will be from eight to a dozen stools each day; I do not pay any attention to this condition of the bowels unless the discharges give mercurial indication. If they do, I then discontinue its use until the stools become less in frequency and when they are again indicated. I was formally led to believe that the disease was occasioned by some alimentary disturbance, but I do not now so believe it to be. I do not believe that the benefit derived from the mercury is due to its action upon the alimentary tract. I do, however, to its action upon the system in general, perhaps in changing secretions which are acids to alkali. The serum exuded from these eczematous patches turns litmus paper red, at least this has been my experience. I think that the successful management of these cases rests in changing the secretion to neutral as I have had many cases make a rapid recovery by the administration of the calomel with the application of simple oil.

A NEW APPLIANCE FOR FRACTURED CLAVICLE.

Read before the Meeting of the National Association of Railway Surgeons, May 25, 1892.

BY JESSE HAWES, M.D.,
OF GREELEY, COL.

I present to you a new appliance to be used as a retentive apparatus in fracture of the clavicle.

Let me modestly state among my first assertions that the appliance probably is not the most valuable contribution that has been made to surgery in the past few years, but its efficiency, neatness, rapidity of application, comfort to the patient, and small cost to the surgeon, commends it in my judgment, formed after using it several years, as superior to any dressing generally known to the profession.

In my remarks I shall premise that a fracture of the clavicle has occurred, has been properly diagnosed, properly reduced, and that we seek the most perfect apparatus for retention.

This paper then will not be an essay upon one of the most frequent fractures of the body, it will not be a treatise upon the clavicle or scapula, or their muscular attachments. I accept the dictum of the majority of surgical writers that the object of a dressing should be to carry the shoulder joint upward and outward and backward.

Premising then that a correct diagnosis has been made, that we seek a dressing that can perform what surgeons have required, I shall ask you to look over with me some of the common appliances and methods, and note the objections that may justly be urged against them, and which in a great measure are obviated by the newer apparatus.

The objection to lying on the back is, that it is a most wearisome and tedious method to which no busy man or woman will submit if they have ever once heard of a method less confining.

Velpeau's dressing remains nicely in place—in a wood-cut only. True, men skilled in the use of silicate or gypsum, may make it a fairly stable and comfortable dressing, but the great majority of men who are called to dress fractures of the clavicle are not skilled in the use of silicate of sodium or gypsum. Ask any expert in the manipulation of plaster of Paris if my statement is not correct. Further, it cannot carry the shoulder upward and retain it there with the ease and comfort of the new dressing.

The objections to the figure of 8 bandage across the shoulders are, that it carries the shoulder backward only, not upward, not outward, that the sound shoulder, which is the point of fixation, is not fixed, but is decidedly mobile, that to be of value it must be taut—and if tight it is almost unendurable.

The shawl as proposed by Dr. Moore of Rochester, has nearly the same objections, and has an additional one that on account of the space occupied by the shawl, the patient must go about the streets dressed in a great-coat.

The axillary pad, used by Bartlett, Fox, Hamilton and others, if used as a fulcrum endangers the brachial artery and nerves—if not used as a fulcrum is better replaced by a pledget of antiseptic absorbent cotton.

Hamilton, after calling attention to the apparatus of Fox, and those similar to it, and after adopting it as a model, declares that notwithstanding the improvements he has added "it is impossible to carry the shoulder out" and almost impossible to carry the shoulder back, and I will add that I cannot understand how it is possible to carry the shoulder well upward and retain it comfortably in that position, either by Fox's apparatus or by Hamilton's modification of it.

The principles and practice of Sayre's dressing are accepted by a large number of surgeons; the majority of surgical works give it an illustration, but it is a sticky, uncleanly, annoying dressing. Further, the weight of the arm and shoulder must be borne wholly upon the olecranon process, or to avoid this, a slit is cut in the adhesive dressing and the weight transferred in great part to the sharp edges surrounding the slit.

Be as careful as I could in dressing fractures after this method I have rarely failed to produce an inflamed elbow. This result perhaps is always the fault of the surgeon, but so long as surgeons shall be wanting in skill, to avoid this a dressing that can secure the best results of the Sayre without its annoyances, must be preferred.

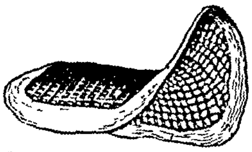

Fig. 1.

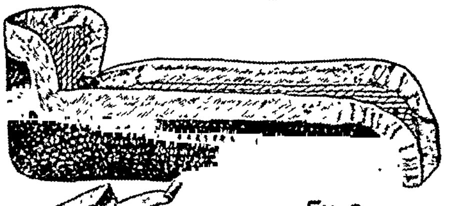

Fig. 2.

Fig. 3.

There is a method of holding the shoulder upward, outward and backward by fastening a cross above the shoulders, of which one arm of the horizontal portion extends beyond the acromion process upon the side of fracture; from the outer end of this point of the cross, a strap extends into the axilla and is used for drawing the shoulder into the ideal position.

I have crucified several persons who were so unfortunate as to have a fractured clavicle, and to entrust themselves to me during my crucifying period, and I here in humility repent. I will crucify no more.

The cross, as I have seen it used, is an instrument of torture. It presses upon the axillary vessels and nerves, it stagnates circulation, it produces numbness. If patiently worn long enough, I believe its strap could tie off the arm as our fathers tied off hæmorrhoids.

The appliance I offer as a substitute for the above dressings consists of three parts, which for convenience of description I shall designate as the arm portion, Fig. 2; the shoulder shield, Fig. 1; and the clavicle depressor, Fig. 3.

The arm portion and the shoulder shield are made of wire screen, described by hardware men as one-quarter inch mesh No. 15 wire.

The clavicle depressor is made of ordinary sheet iron.

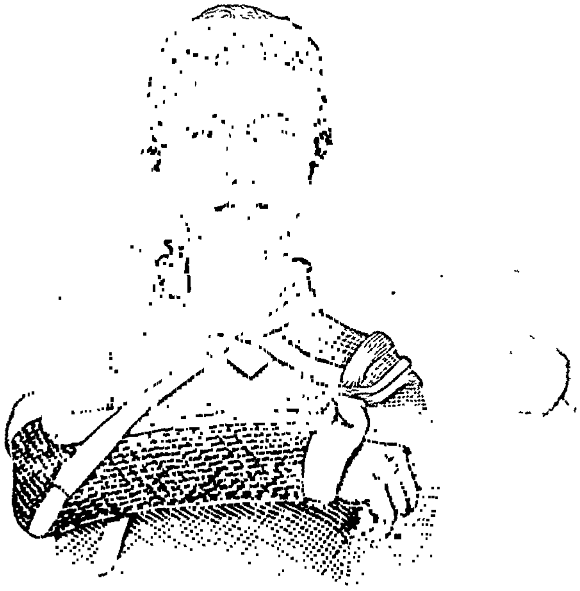
The arm portion for the average adult is made from a piece of screen about sixteen inches long and eight inches wide.

It should be so formed as to loosely encircle three-fourths of the bent arm from the wrist to a point four or five inches above the elbow.

The radial surface of the arm is not enclosed. The texture of the screen is such as to permit it to be molded quite easily into the form we desire by any ordinary tinsmith.

The arm piece should be deeply indented opposite the olecranon process and the condyles, to avoid all pressure at these points. The margins of the piece can be easily covered by ordinary rubber adhesive plaster.

A strong piece of webbing or belting or roller bandage is attached to the outside of the splint near the olecranon prominence. It should be so long that when the arm piece is applied to the arm, the webbing can pass obliquely across the back and over the opposite shoulder where it is buckled to its opposite end.



A similar piece of webbing is sewed to the distal or manual end. The arm piece is to be applied to the arm corresponding to the injured bone.

A soft [illegible] should line the arm piece. The shoulder shield is placed on the shoulder opposite to the fracture, and should be molded to its contour. A soft pad should be beneath it when in position.

The diagnosis of fracture of clavicle having been made, the arm corresponding to the injured side is cradled in the arm portion of the dressing, then the belt sewed to its olecranon end is carried through the axilla, over the scapula over the opposite shoulder, protected by its shield, and is buckled to its opposite end.

Now grasp the wire appliance at its elbow and push the shoulder upward, outward, backward, and tighten the belt until it retains the shoulder in the position where placed.

Carry the manual belt through the axilla over the shield, tighten until the hand is brought near to the shoulder, and in most cases this is all that will be necessary to do until the dressing is permanently removed and the patient discharged.

The olecranon strap will hold the shoulder upward and backward, the manual belt will, by drawing the elbow inward across the chest, make of the breast a fulcrum as safe as we can use or will need.

Indeed when the shoulder is carried upward and backward sufficiently, the fractured ends can be nicely approximated and there will be little desire of carrying the shoulder outward.

I have spoken of a clavicle depressor. In many cases it will not be necessary. In a few where it is aimed to secure the least possible deformity it will be of material advantage.

It is made of a piece of sheet iron an inch wide, and about six inches long, bent inward a little above its center sufficiently to reach over the clavicle, the upper end extending about two inches above the clavicle; this must be padded and a strip of adhesive plaster may be sewed to the padding.

To hold this in position and to depress the clavicle, I have resorted to the following device:

Sew a short strip of elastic webbing upon a strip of rubber adhesive plaster, sew a buckle to the webbing, hold the buckle opposite the clavicle, draw the plaster and webbing vertically downward directly over the depressor, stick the plaster to the skin of the chest. Apply a similar elastic and adhesive plaster (without the buckle) in the line of the depressor down over the scapula, buckle the two elastics over the depressor.

The amount of force necessary to depress the clavicle can be regulated as desired.

In presenting this appliance for your consideration, I desire to direct attention to what I regard as its chief merits.

By its use the ordinary adult shoulder can be carried upward and *retained permanently* and *comfortably* at an elevation of from one and one-half to two and one-half inches above its ordinary position.

Elevating the arm when the elbow is carried forward and inward carries the shoulder backward and slightly outward.

The posterior portion of the olecranon strap, in its course from the elbow to the opposite shoulder, passes over and binds down the scapula of the injured side. This is regarded as important by many surgeons.

The heavy wire indented as directed above, removes all pressure from the olecranon and condyles, and transfers it to a part where it is easily borne.

The belt carried from the base of the neck to the opposite shoulder is nearly vertical, and more certainly assures an upward lifting of the arm and shoulder than the Sayre appliance, which, lifting from the point of the shoulder, exerts its force more obliquely and therefore less efficiently.

The shoulder shield protects the tissues of the neck and shoulder from injurious or uncomfortable pressure.

A single arm piece and shield is suitable for a wide range in size of arms and shoulders. The form is easily changed.

There is no pressure upon the nerves and vessels of the axilla. The dressing is applied almost in a moment, and will not get misplaced. It is cleanly.

It is cheap. An arm piece, shield and depressor, without webbing and without the adhesive plaster on edges, should be furnished by the tinsmith at a cost not to exceed *fifty* cents.

SCARLET FEVER WITH NEPHRITIS IN PREGNANCY.

BY F. A. COGSWELL, M.D.,

OF SWALEDALE, IA.

Scarlet fever occurring in the pregnant woman seems to be a pathological rarity which is accorded but scant space in every treatise which the writer of this paper has had opportunity to examine.

While the parturient woman is said to be very susceptible to infection during epidemics of scarlet fever, but very few cases of this disease occurring during the period of gestation are recorded.

The belief of the older obstetricians that pregnant women possessed immunity in a certain degree from acute infectious diseases having been abandoned by most writers of the present day, and thus establishing the rule that women during gestation are as liable to attacks of scarlet fever as at any other period of adult life, we are somewhat at a loss to account for the exceedingly small number of recorded cases.

Cazeaux never saw a case.

The American System of Obstetrics tells us that Olshausen collected 7 cases. Pregnancy was interrupted in four of these. In certain cases the disease was transmitted to the fœtus.

Quoting from the Cyclopedia of Obstetrics we find that scarlet fever appears to be the exception during pregnancy. When occurring it assumes a grave, *malignant* type, and terminates in abortion in the case of *every* woman, in *death* in the *majority.*

Austin Flint speaks of a case where the patient contracted the disease in the seventh month of pregnancy. Miscarriage occurred during the period of *incubation.* Parenchymatous nephritis occurred as a complication, and although the symptoms denoted great danger, the patient recovered and the child lived.

Parvin, in the Handbook of Medical Science says: "Scarlet fever is rarely observed in pregnancy and when it does occur is liable to interrupt its further progress, and is peculiarly fatal."

Jaggard in an article on "Acute Infectious Diseases in Pregnancy," says they are of the gravest clinical importance. Have a marked tendency to cause abortion with great peril to the mothers. Hæmorrhagic endometritis during infectious diseases is not uncommon in the non-gravid state and is more common in the pregnant condition."

He further says that during the progress of infectious diseases, death of the fœtus and consequent abortion may be caused.

First.—By the elevation of the maternal temperature which produces a disproportionate rise in the temperature of the unborn child. As one author says, "it dies of heat-stroke."

Second.—It may die from asphyxia caused by lowering of the maternal blood pressure, or by structural changes in the epithelium covering the fœtal placenta due to the condition of the maternal blood.

Third.—It may perish in consequence of infection with the specific poison of the disease, and

Fourth.—It may be expelled on account of thermic irritation of the uterine muscular fibre.

Bearing these causes in mind and referring to the case reported by Flint the question arises as to what caused the miscarriage to occur during the period of incubation.

Spiegelberg says, "The eruptive fevers usually occur early in pregnancy, but the tendency to malignant forms with fatal results increases as pregnancy advances."

The experience which prompted the writing of this paper began on February 28, of the present year.

Mrs. C., æt. 25, in the latter part of the sixth month of her second pregnancy, had been suffering for 24 hours with tonsillitis which was epidemic at that time. Vomiting and diarrhœa had occurred, but were attributed to the fact of pregnancy. On the day before mentioned a brilliant, thick set scarlet rash was discovered which soon covered almost the entire body. Having heard it said during our college days that young doctors were famous for finding cases of rare diseases, an older practitioner, Dr. E. C. Miller, of Rockwell, was sent for, who unhesitatingly agreed in the diagnosis of scarlet fever, a malignant form of this disease being in the locality. The angina became very painful, and the rash was as typical as any the writer has ever seen. The temperature, however, never rose above 101½° F. at any period of observation. In the course of five or six days the rash disappeared, although the soreness and swelling of the throat persisted a few days longer. No other complications occurred up to this time, and not a particle of desquamation was discoverable at any time. The patient gradually returned to her apparent usual health and was soon up and about the house.

On returning home from a protracted country trip at 2 A.M., on March 15, the patient was found very sick with all the symptoms of acute nephritis. Chill, fever, pain in the back, aching of the body, feet and legs much swollen, and face so bloated as to be almost unrecognizable. Tongue broad, pale, flabby and covered with a white, pasty coat. Pulse 120. Urine nearly suppressed, dark brown in color, with a sooty deposit. Not over eight ounces was passed in the first 24 hours. Sp. gr. 1012, considerable albumen. By the third day urine was a clear blood red, slightly increased in quantity, sp. gr. same as before. Headache, with irritability, and dulness of mind, and dimness of vision now appeared as part of the clinical picture. This condition, with slight increase in amount of urinary discharge, sp. gr. varying from 1010 to 1012, color blood red, but growing paler, amount of albumen about as at first, persisted for ten days.

At this time patient began to improve in all respects and at last examination of urine on April 10, the quantity was normal, color natural and no albumen. Nearly every trace of swelling had disappeared. Tongue was red, full and round. No coating. There was a considerable diminution in body weight, also in size and firmness of muscular structures. A certain amount of dyspnœa, of which the patient had complained for some time prior to the attack of scarlet fever was now gone, and she said she had not felt in better health for years.

The treatment during the scarlet fever was of the usual kind. Diet of milk and beef juice.

During the nephritis, tinc. of iron, tinc. digitalis, potass. acet, saline cathartics, tonic doses of quinia and strychnia, and lactopeptine were administered. A few doses of morphia, bromides and chloral were given to quiet pain and restlessness.

During the first twelve days the diet was *exclusively milk.*

No symptoms of convulsions or abortion appeared.

During the interval between the fever and the onset of the nephritis the patient resumed her usual diet, and here a mistake was made, as the milk diet should have been continued until danger of kidney complications was past. The patient also should not have been allowed to expose herself to varying temperatures as she did. Urinary examinations should have been made and thus have anticipated in some degree the possible violent nephritic attack.

On June 8, the patient was normally delivered of an 8½ pound boy. Return to health has been rapid and satisfactory.

Among various queries which have arisen in the mind of the writer regarding this case, are the following: To what extent did the medicinal treatment contribute to the favorable termination of the nephritis; and, is the child subject to future scarlatinous infection?

PURULENT BRAIN DEPOSITS, AND PHLEBITIS AND THROMBOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

BY FRANK ALLPORT, M.D.,
OF MINNEAPOLIS, MINN.,
PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLOGY IN THE UNIVERSITY OF MINNESOTA, ETC.

(Concluded from page 728.)

The pus may be found outside of the dura-mater, and search should be made for it in this location. If found, and the dura appears to be thoroughly healthy, with no bulging or fluctuation, the operation may cease, and future developments awaited. But if pus is *not* found outside of the dura, or when found in this situation the dura appears unhealthy, or bulges or fluctuates, a free incision through it should be made, and the brain itself exposed. Pus may be found just inside the dura. If this proves to be the case, and the brain substance appears healthy, and is not bulging or fluctuating, operations may be suspended; but if pus is not found, or, if found, and the conditions just mentioned are present, and the operator is reasonably sure of his diagnosis, investigations must be pushed into the brain proper.

For exploring the brain, the aspirator, or exploring needle is to be preferred to the knife, and it should be introduced, and re-introduced, again and again, rather than to shove it along, from place to place, in hopes of finding pus. When the abscess is reached, the knife may be used to freely lay it open, at its most dependent portion. This cavity should not be syringed, a thorough opening, and good drainage being sufficient. A few strands of gut, should be placed into the abscess, as far as can be reached, and the end allowed to hang outside of the head. This can be shortened from day to day.

The dura-mater, and skin flaps, may be sutured at their upper portions, but enough space at the bottom allowed to remain open, to admit of good drainage.

Gut sutures should be employed for uniting the dura-mater, and iodoform dressings should be employed. Lanphear recommends that the head should be kept low after the operation, and it is needless to say that the strictest antiseptic precautions should be maintained.

In case it becomes necessary to attack the cerebellum, the same directions are applicable, and the only question is to ascertain the best point for trephining. The opening should be made in the cerebellar fossa. This disease does not usually occur sporadically in the cerebellum, but spreads backwards, *to* the cerebellum from the usual focus of disease, viz.: the petrous and mastoid portions of the temporal bone, in consequence of which the abscess will generally be found in the anterior portion of the cerebellum. We must get at this portion of the brain, to do which the opening must be made one and a half inches back of the middle of the osseous meatus, and one-quarter of an inch below it. The opening, in other words, should be just back of the posterior border of the mastoid process. The lateral sinus would not be touched at this point, and the exploring needle should be directed upward, forward, and inward, to reach pus in the anterior portion of the lateral cerebellar lobe.

Before passing on to a consideration of phlebitis and thrombosis, I beg leave to submit the following tables, compiled from a study of the foregoing cases.

We first have a complete list of the symptoms and conditions occurring in the histories recorded in this article, and the frequency of their occurrence. They are as follows:

Deafness	11	Temperature high	8
Tinnitus aurium	3	Temperature medium	42
Tympanic necrosis	6	Temperature sub-normal	2
Tympanic granulations	6	Pulse high	6
Tympanic polypus	7	Pulse medium	33
Ear pain	35	Pulse sub-normal	2
Cholesteatoma	3	Sudden rise and fall of temp.	2
Swelling in front of ear	3	Chills	38
Swelling over ear	4	Facial paresis or paralysis	28
Swelling under ear	4	Paresis or paralysis, limbs	19
Mastoid swelled and tender	35	Spasms of limbs	7
Mastoid opened, spontaneously or otherwise	31	Spasms of facial muscle	4
		Paralysis of auditory nerve	2
Pus found in mastoid after opening	16	Suspended breathing	1
		Incontinence of urine	3
Pus *not* found in mastoid after opening	7	Facial veins enlarged	2
		Optic neuritis	11
Spontaneous mastoid opening	5	Amblyopia	5
		Amaurosis	1
Wilde's incision made	9	Syncope	2
Opening into cranium made either spontaneously or otherwise	21	Neuralgia of trigeminus	2
		Epilepsy	4
		Head pain	78
Pus found in cranium after opening	16	Diplopia	2
		Strabismus	10
Œdema of eyelids	1	Tender spine	1
Pupils dilated	8	Epistaxis	1
Pupils contracted	8	Diarrhœa	3
Pupils sluggish	2	Constipation	11
Nystagmus	1	Pyæmia	4
Ptosis	6	Episthotonus	3
Exophthalmus	4	Meningitis	10
Delirium	36	Nausea and vomiting	41
Aphasia	8	Facial œdema	2
Stupor	18	Facial herpes	2
Unconsciousness	17	Œdema of neck	3
Coma	39	Maniacal	1
Convulsions	22	Vertigo	22
Insomnia	2	Fainting	1
Somnolence	11		

I have given this itemized record of symptoms, as they have come to me in the reports. It would seem that the histories must have been given somewhat inaccurately, as I feel confident that many of the symptoms must have been of more frequent occurrence.

For instance: head pain, ear pain, deafness, tympanic necrosis, etc., must have been present in most of the cases, and yet it is not here recorded. On the contrary, some of the symptoms noted, were so seldom seen and apparently have so little direct bearing on the case, that they can hardly be classed in the symptomotology of intra-cranial disease following aural affections.

As to the results obtained in these cases, the record is as follows: Death, 158; recovery, 11. Total, 169.

We find that in these 169 cases, the skull has been opened spontaneously or otherwise, 21 times. All the 11 recoveries here recorded are contained in these 21 cases after the skull has been trephined, and the brain exposed. This shows a recovery of more than one-half of the cases thus operated. Considering our primitive knowledge of the subject, this record is good, and should encourage us to renewed efforts in the future, especially as operative interference is our only reasonable hope for lessening the mortality.

I will now beg leave to submit an itemized report of the various post-mortem appearances found, and the frequency of their occurrence. They are as follows:

Pus in the dura-mater	1
Pus in the pia-mater	7
Pus in the arachnoid	1
Pus in the superior petrosal sinus	2
Pus in the lateral sinus	5
Pus in the jugular sinus	2
Pus in the sigmoid sinus	3
Pus in the inferior cavernous sinus	2
Pus in the internal jugular vein	1
Pus in the lateral ventricle	4
Pus in the posterior occipital fossa	1
Pus in the middle cranial fossa	1
Pus in the 1st frontal fissure	1
Pus in the fissure of Rolando	1
Pus in the neck	2
Pus around chiasm	1
Pus over temporal lobe	1
Pus over medulla	4
Pus over pons	2
Pus between mastoid and dura-mater	1
Pus around spinal cord	1
Pus on surface of cerebellum	2
Pus between dura-mater and tegmen-tympani	3
Pus generally distributed over side of hemisphere	15
Pus on opposite side of brain to point of lesion	1
Pus in mastoid cells	15
Pus in labyrinth	1
Pus in cochlea	2
Pus in Fallopian canal	1
Pus in Eustachian tube	1
Pus in tensor tympanic canal	1
Pus patches over brain	2
Pus at base of brain	2
Pus at sella turcica	1
Pus on outer surface of frontal convolution	4
Purulent meningitis	11
Purulent bas. meningitis	3
Purulent lepto-meningitis	3
Purulent infiltration of orbit	1
Pus in semi-circular canals	3
Pus in tympanum	22
Pus in vestibule	4
Pus in internal ear	2
Pus in mastoid antrum	5
Pus on outer mastoid surface	2
Pus on outer squamous surface	1
Pus on outer sup. max. surface	1
Abscess in temporal lobe	40
Abscess in middle lobe	7
Abscess in occipital lobe	1
Abscess in frontal lobe	2
Abscess in cerebellar lobe	31
Abscess in pons	3
Abscess in crus cerebelli	1
Abscess in middle cranial fossa	1
Abscess in post. cranial fossa	2
Abscess in 1st frontal convolution	1

Abscess at apex of petrous	1
Abscess beneath dura-mater on outer surface of petrous	3
Diffuse sub-dural abscess	5
Abscess encapsulated	9
Abscess not encapsulated	2
Necrosis of upper part of petrous	10
Necrosis of inner surface of squamous	3
Necrosis of inner table of skull (general)	1
Necrosis of outer surface of mastoid	6
Necrosis of outer sarface of occip.	1
Necrosis of outer surface of sup. max	1
Necrosis of outer surface of frontal	1
Necrosis of outer surface of squamous	3
Necrosis of outer surface of parietal	2
Necrosis of inner surface of mastoid	5
Necrosis of mastoid antrum	6
Necrosis of mastoid cells	11
Necrosis of tympanum	21
Necrosis of tegmen-tympani	16
Necrosis of malleus	1
Necrosis of incus	1
Necrosis of meatus ex.	8
Necrosis of cribriform lamina.	1
Necrosis of jugular fossa	1
Necrosis of cochlea	1
Necrosis of vestibule	1
Necrosis of semi-circular canals.	3
Necrosis of pyramid	1
Necrosis of lateral sinus	5
Necrosis of bony wall of facial canal	1
Necrosis of vertebræ	2
Necrosis of sulcus for lateral sinus	2
Necrosis of bony wall of carotid canal	2
Necrotic opening through roof of mastoid antrum	2
Necrotic opening through squamous	1
Necrotic opening in bony wall of sulcus trans.	1
Necrotic opening in incis. santorini	1
Necrotic opening in sup. pet. sinus	1
Necrotic opening in wall of lateral sinus	2
Necrotic opening in parieto-occip. suture into cranial cavity	1
Necrotic opening in semi-circular canals	2
Necrotic opening in sigmoid flexure.	1
Necrotic opening in posterior wall of meatus	1
Necrotic opening between middle and internal ears.	2
Necrotic opening between internal ear and cranial cavity	2
Necrotic opening between mastoid antrum and sup. pet. sinus	1
Necrotic opening between mastoid antrum and sigmoid sinus	2
Necrotic opening in tegmen-tympani.	13
Necrotic opening through anterior surface of petrous.	1
Necrotic opening through lower tip of mastoid	1
Necrotic opening through inner mastoid plate to lat. sinus	5
Necrotic opening through outer mastoid plate.	1
Necrotic opening through inner mastoid plate.	1
Thrombosis in long. sinus.	8
Thrombosis in superior petrosal sinus.	9
Thrombosis in inf. petrosal sinus	2
Thrombosis in sigmoid sinus	1
Thrombosis in lateral sinus	8
Thrombosis in transverse sinus	8
Thrombosis in cavernous sinus	3
Thrombosis in carotid sinus	2
Thrombosis in sub. clav. vein	1
Thrombosis in internal jugular vein	9
Thrombosis in basilar vein	1
Thrombosis in ophthalmic vein	1
Thrombosis in bulb. ven. jug	1
Thrombosis in sigmoid flex	1
Thrombosis in circular sinus of Ridley	1
Phlebitis of lateral sinus	4
Phlebitis of trans. sinus	4
Phlebitis of superior petrosal sinus	1
Phlebits of ex. jug. vein	3
Phlebitis of mastoid em. vein	1
Phlebitis of ophthalmic veins	1
Dura-mater inflamed	11
Dura-mater perforated	8
Dura-mater adherent to bone	6
Arachnoid inflamed.	2
Pia-mater inflamed	12
Pachymeningitis	1
Bas. meningitis	7
Tuberc. meningitis	3
Meningitis	14
Lepto-meningitis	1
Brain membranes adherent to each other	3
Congestion of all meningeal veins.	1
Hernia of temporal lobe.	1
Gangrene of brain	2
Ossicles gone (all)	7
Malleous gone	6
Incus gone	8
Stapes gone	5
Drum-head gone	12
Drum-head perforated	3
Drum-head not perforated	1
Polypus in tympanum.	6
Cholesteatoma in tympanum.	4
Epithelioma in tympanum	1
Granulations in tympanum	3
Facial nerve destroyed	5
Facial nerve exposed and imbedded in pus	3
Auditory nerve exposed and imbedded in pus	1
Cholesteatoma of mastoid antrum	2
Granulations of mastoid antrum	2
Cholesteatoma of mastoid cells.	2
Mastoid cells sclerosed	5
Mastoid cells obliterated	3
Auricular glands enlarged	1
Sigmoid sinus obliterated	1
Bulb. portion of jug. vein obliterated	1
Mastoid em. vein obliterated	1
Chorda tymp. nerve obliterated	2
Trigeminus nerve obliterated	1
Atrophy of op. nerve	2
Frontal lobe œdematous and soft	1
Adhesions between brain and skull	4
Polypus of external meatus	1
Rupture of sigmoid sinus	1

Having now considered the subject of purulent accumulations within the cranial walls, resulting from otorrhœa, we will turn our attention to "Phlebitis and thrombosis of the cerebral veins and sinuses, caused by otorrhœa."

The two subjects of phlebitis and thrombosis may be considered under one head, as the symptoms and conditions are identical, excepting that the evidences of disease are more marked and decided in thrombosis than in phlebitis. The principal sinuses and veins affected are the lateral, cavernous, superior longitudinal, and superior and inferior petrosal sinuses, and the mastoid emissary and facial veins. The parts drained by these sinuses and veins show with tolerable distinctness the seat of the trouble. I will itemize the special local symptoms that follow phlebitis and thrombosis of each of these sinuses and veins.

If the lateral sinus is affected we will be apt to notice tenderness, œdema, and a corded feeling along the course of the internal juglar vein in its course towards the clavicle. Sometimes purulent degeneration of these parts wil be seen, while œdema of the parts in and about the external ear, dizziness, and staggering, may be expected.

By union of the two lateral sinuses at the internal occipital protuberance, the difficulty may extend from one sinus to the other, and thereby produce at the opposite side, the same condition existing at the original site of disease.

If the cavernous sinus is affected, we may anticipate œdema of the retina, poor vision, photophobia, œdema around the eye, and in the orbit; œdema of nostrils, forehead, eyelids, and nasal mucus membrane, epistaxis, perhaps exophthalmus, ptosis, sloughing of orbital tissue, paresis or paralysis of the abducens, oculo-motor and trigeminus nerves.

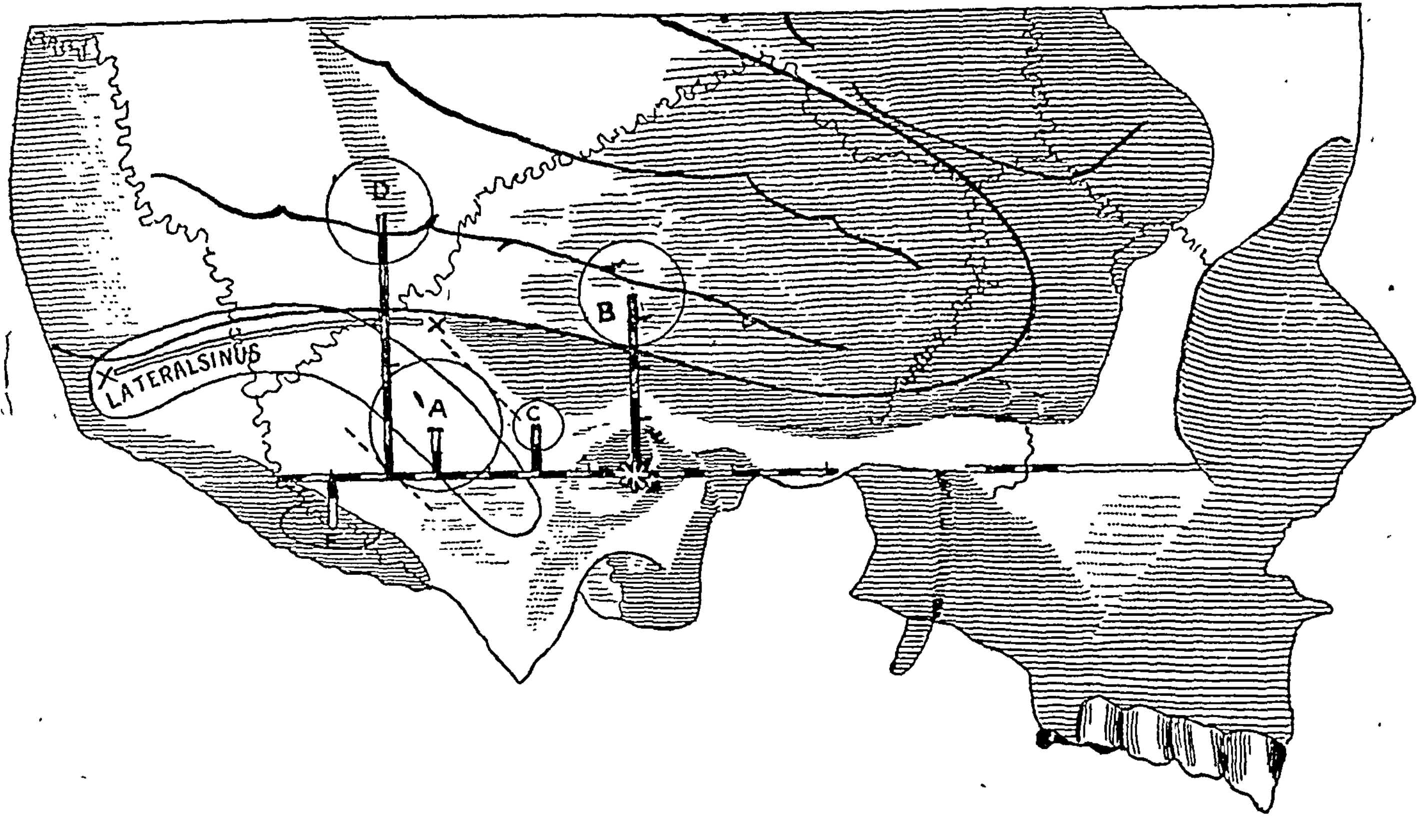
If the superior longitudinal sinus be affected, we may look for epistaxis, epilepsy, convulsions, and vascular engorgement in the cortical substance of the cerebrum, producing unconsciousness.

If the superior or inferior petrosal sinuses be affected, we may expect epistaxis, swelling of veins extending from the anterior fontanelle to the temples, epilepsy, engorgement of orbital vessels, poor vision, photophobia, paresis or paralysis of oculomotor and abducens nerves, exophthalmus, ptosis, œdema of eye-lids, and sloughing of orbital tissues.

If the mastoid emissary vein be affected, we will usually notice induration of the neck and suppuration of the induration, œdema around mastoid process, tenderness over exit of mastoid emissary and jugular veins, suppuration over the former, œdema of eye-lids, purpuric spots on face and upper part of chest (this is usually one of the latest symptoms) general head pain, vomiting, coma, convulsions, facial erysipelas, dyspnœa and delirium.

If the facial vein is affected, we expect œdema of face, erysipelatous swelling of cheeks and eye-lids, and possibly vesicles on face.

It will be noticed that some of the symptoms here given, are the same, when different vessels are involved, this being due to the connection existing from one vessel to the other, and in consequence the almost necessary implication of more than one portion of the venous circulation at a time. A correct idea as to the original seat of disease, must be estimated by a review of the different conditions, with a careful elimination of the less predominating symptoms.



LATERAL ASPECT OF A SMALL ADULT SKULL. NATURAL SIZE. (FROM BALLANCE.)

The illustration shows the relations of the lateral sinus to the outer wall of the cranial cavity, and the position of the trephine opening (A) which should be made when it is deemed necessary to expose it. The base line (Reid's) passes through the middle of the external auditory meatus and touches the lower margin of the orbit. It is marked out in eighths of an inch, as are also the perpendicular lines drawn from it. The measurements are made along the base line from the middle of the bony meatus. The drawing also shows the convolutions of the temporo-sphenoidal lobe, the Sylvian fissure, and the position of the lower end of the furrow of Rolando. XX indicates the site of the tentorium as far as it is in relation to the external boundary of the skull. The anterior X shows the point where the tentorium leaves the side of the skull, and is attached to the superior border of the petrous bone. A, trephine opening to expose sinus, ⅝ inch in diameter, its center being 1 inch behind and ¼ inch above the middle of the bony meatus. This opening can easily be enlarged upward and backward and downward and forward (see the dotted lines) by suitable angular-cutting bone forceps. It is always well to extend it forward, so as to open up the mastoid antrum (C) and the gutter of the carious bone (if there be one) which leads from the antrum, tympanum, or meatus, down to the bony groove. The position of the trephine openings which must be made for the relief of inflammatory intra-cranial affections secondary to disease of the ear other than for sinus pyæmia have been added to the drawing for the sake of contrast and completeness. They are as follows: B, trephine opening to explore the anterior surface of the petrous bone, the roof of the tympanum, and the petro-squamous fissure. ½ inch in diameter, its center being situated a short inch (⅞ inch) vertically above the middle of the meatus. At the lower margin of this trephine hole a probe can be insinuated between the dura and bone, and made to search the whole of the anterior surface of the petrous. C, trephine opening for exposing the mastoid antrum, ¼ inch in diameter, and ½ inch behind and ¼ inch above the center of the meatus; or ¼ inch above the center of the meatus and ¼ inch behind its posterior border. The trephine should be directed inward and slightly downward and forward. When a superficial disk of bone has been removed, it is well to complete the operation with the gouge. A large trephine may with advantage be employed, especially in adults. D, trephine opening for temporo-sphenoidal abscess, ½ inch in diameter. Situation recommended by Barker, 1¼ inches behind and 1¼ inches above center of meatus. The needle of the aspirator is to be directed, at first, inward and a little downward and forward. E, trephine opening for cerebellar abscess, ½ inch in diameter, and 1½ inches behind and ¼ inch below the center of the meatus. The anterior border of the trephine should just be under cover of the posterior border of the mastoid process. The drawing shows that a trephine hole made in this situation is far away from the lateral sinus, and that the trocar and canula of the aspirator, if directed forward, inward and upward, would hit an abscess occupying the anterior part of the lateral lobe of the cerebellum, which is the usual site of collections of pus in this part of the brain.

Besides these special indications of disease in the various vessels, there are some general symptoms of phlebitis and thrombosis of the cerebral sinuses and veins following otorrhœa, that must not be forgotten.

The general appearance of a patient suffering from this disease, is apt to be quite different from that of a person afflicted with purulent accumulations in the brain cavity. Of course it must not be forgotten that the two conditions may be combined in one case, in which instance, a mixture of both symptoms will be observed. The general appearance of a patient suffering from cerebral pus deposits. pure and simple, is not *active*. The disease kills insidiously; the condition is below par. The temperature and pulse are not much exalted; they may even be sub-normal. If the mental condition is disturbed, it is apt to be in a dull apathetic manner, and the entire appearance is usually one of depression and anxiety.

Phlebitis and thrombosis, on the contrary, induce a different state of affairs, and the patient appears exhilarated, and in a nervous, highly-strung condition. The temperature is never sub-normal, and is apt to be high, with occasional rapid changes from a medium to a high degree. Chills are of frequent occurrence. Violent delirium is sometimes seen, and the scarlet cheek and brilliant eye, denotes an exalted condition, and a rapid progress towards a fatal termination.

There is one symptom that I find recorded but twice in these 169 cases, where the post mortem each time revealed the same pathological condition. This symptom was a sudden rise and fall of temperature. The autopsy in both instances, showod a thrombosis in the lateral sinus, and internal jugular vein, and while not attaching too much importance to these symptoms and conditions, they should not be entirely forgotten.

I beg leave to here submit a chart with descriptive remarks, that I take the liberty of borrowing from Ballance. It is extremely simple and accurate, and will be found invaluable in elucidating the topography of the brain, skull, etc.

I have tabulated the symptoms occurring where phlebitis and thrombosis were present, and beg leave to submit them.

Head-pain	12	Optic neuritis	1
Ear-pain	2	Œdema of lids.	3
Temp. medium.	4	Diplopia	1
Temp. high.	3	Facial herpes.	1
Pulse medium	4	Facial paralysis	3
Pulse high	3	Facial veins enlarged.	1
Chills	11	Vomiting and nausea	5
Mastoid tender and swelled	5	Neck swelled and painful	6
Delirium	9	Pyæmia	3
Unconsciousness	1	Diarrhœa	1
Coma	3	Epistaxis.	1
Stupor.	1	Sudden rise and fall of temp.	2
Somnolence.	1	Exophthalmus.	3
Convulsions.	1	Œdema near ear	1
Vertigo	3	Meningitis	1
Strabismus.	2	Œdema of uvula.	1
Amblyopia	2		

I have also prepared a table showing symptoms that occur in *pure* cases of phlebitis and thrombosis, uncomplicated by any brain lesion.

These symptoms do not occur in any other class of cases under consideration:

Œdema of eye-lids
Facial veins enlarged.
Pyæmia.
Diarrhœa.
Epistaxis.
Sudden rise and fall of temp.
Œdema near ear.
Œdema of uvula.

I have also noted the symptoms found in both kinds of cases, viz.: Cerebral pus deposits, and cerebral phlebitis and thrombosis, following otorrhœa, but predominating in the latter. These are as follows:

Chills.
High Temperature.
High Pulse.
Episthotonus.

Records like these are significant, but too much reliance must not be placed upon them, as some of these symptoms may have been incidental only. We must naturally bear in mind in estimating these records, as to symptoms and post-mortem appearances, that some observers are more accurate than others in noting and recording such items, and in consequence the reports may not always be thoroughly correct. It is, however, in a large number of cases, comparatively easy to see the general drift, in favor of certain symptoms, post-mortem appearances etc. Again, many of the symptoms and post-mortem appearances are not at all significant, and hardly noteworthy. Their infrequent occurrence, and evident irrelevancy, deprive them of importance, and really make them unworthy of consideration. The principal symptoms, and the important seats of lesion, should be born in mind, but further than this we need not go.

Phlebitis and thrombosis as heretofore specified, may be caused by direct contact of necrosed bone, with the capsule of the vessel, by contiguity of tissue along the vascular walls, or by means of pus migration through the small bony foramenæ, or the various vascular supplies.

It may be well, therefore, to briefly glance at some of the essential anatomical points involved in the matter, and for this purpose I take pleasure in referring somewhat to the studies and researches of Green, Bacon and Dana.

A close relationship exists between the cerebral veins and sinuses and the focus of disease in otorrhœa. For instance, the veins of the tympanum terminate in the middle meningeal and pharyngeal veins, and pass from thence to the internal jugular vein.

The lower floor of the tympanum separates this cavity from the jugular vein, and is perforated by the glosso-pharyngeal nerve and a minute vessel.

The mastoid cells are separated from the lateral sinus, by a thin osseous wall, which is perforated by minute foramenæ. It will be remembered, that the veins of the vestibule and semi-circular canals, accompany the arteries, and receiving those of the cochlea, at the base of the modiolus, terminate in the superior petrosal sinus.

There are eight emissary veins passing through the skull, which connect the organs and tissues in the interior of the skull, with those exterior to it. It is not essential that all of these should be mentioned, but the mastoid emissary vein is by far the most important. It emerges from the skull just behind the mastoid process, and furnishes a venous connection, between the lateral sinus and the occipital veins, outside of the skull. It passes through the mastoid foramen, and connects the lateral sinus with the occipital veins, and goes from thence to the internal jugular vein. Greene asserts that, its average position is just behind the posterior limit of the *mastoid process*, about on a line with the meatus. Its position is important, because it is at this point, that we may first notice the swelling, pain and tenderness that indicates an involvement of the lateral sinus. The condyloid emissary vein passes through the condyloid canal, and connects the plexus verteb. cervical., with the lower end of the lateral sinus. The parietal emissary vein passes through the parietal foramen, connecting the veins of the scalp, with the superior sagittal sinus. The occipital emissary vein, passes through an opening in the occipital protuberance, and connects the occipital veins with the sinus near the torcular herophili.

It should also be remembered, that the vascular supply of the scalp, skull, and dura-mater comes from the external carotid, while the vascular supply of the eye, brain, and pia-mater, comes from the internal carotid and vertebral veins.

My records show that the longitudinal, superior petrosal, lateral and transverse sinuses, and internal jugular vein, are affected by phlebitis and thrombosis, with about equal frequency, and that these sinuses and veins are more frequently affected than any others.

From these statistics it does not appear that the lateral is more frequently affected than the other sinuses, as is generally believed. Indeed, the superior petrosal sinus was found thrombotic once more than the lateral sinus, which would lead us to infer that this disease is somewhat more inclined to spread from the middle and internal ears, than from the mastoid cells.

The frequency of involvement of the internal jugular vein, is accounted for by the easy transmission of disease from the middle and internal ear by three channels. One by the tegmen-tympani, another by a small vein passing from the middle ear into the middle meningeal vein, and thence to the internal jugular vein, with still another means of communication by the veins before mentioned passing from the internal ear, into the superior petrosal sinus, into the lateral sinus, and into the internal jugular vein.

The venous connection between the mastoid cells, and lateral sinus; which in its turn empties into the internal jugular vein, must not be forgotten in this particular, and we therefore infer it to be but natural that the internal jugular vein should be frequently affected, as it is the dumping ground of so many venous channels.

These cases run a variable course, extending from a few hours to several weeks, but the result is usually fatal, although instances of recovery are not rare. I myself have seen several cases, of undoubted phlebitis and thrombosis, of a most severe character, where complete and permanent recoveries have occurred.

Postmortem examinations have produced frequent cases of brain thrombi, where such a condition was not suspected during life. The explanation of this phenomenon is probably the vicarious action of the rich collateral circulation. Barr reports a case where the autopsy showed complete occlusion of the lateral sinus, by fibrous bands.

Death usually takes place from metastasis, especially by embolic pleura-pneumonia, less frequently by abscess of the liver and kidney, sometimes from pyæmia. We may be sure of a fatal issue, when thrombus of the internal jugular vein is found, with metastasis of the internal organs.

We have gathered that phlebitis and thrombosis of the cerebral sinuses and veins from otorrhœa is not so fatal in its character, as cerebral abscesses, etc., from the same cause, and consequently the indications for operation, are not so imperative. We can often afford to temporize somewhat with it, treat the indications and wait for developments and active indications, before resorting to operative procedures. This is fortunate, as it is difficult to get at the focus of disease in many instances, and our methods of operation are far from being crystalized.

We may first endeavor to remove the focus of disease in the middle ear. This may be done by opening abscesses, removing granulations, polypi, or necrosed bone, and by the use of quiet, aural douches of hot water, combating any incidental conditions that may arise, and the free use of alteratives, and absorbents, such as mercury and the iodides. If these measures fail, and the symptoms continue or grow worse, the mastoid process should be freely opened, even though no signs of disease be here present.

If now, after awaiting a reasonable length of time, the symptoms show no sign of abating, we must direct our operations directly to the sinus or vein involved. If thrombus of the lateral sinus is found, the internal jugular vein should be tied at two points in the neck, and the intervening vein tissue removed, after which the surrounding parts should be thoroughly cleansed, etc. This procedure is necessary as an obstacle against the passage of the septic material into the general circulation.

The lateral sinus may now be exposed, by opening the skull one inch behind, and a quarter of an inch above the centre of the bony meatus. A free opening should be made, the diseased area thoroughly and antiseptically cleaned, and unhealthy tissue removed, after which it should be packed with iodoform gauze.

Ballance says that after the jugular is tied the face and lips become blue, but that it is only temporary.

Surgical interference upon the other sinuses and veins is not sufficiently crystallized to warrant extended remarks.

THE ACTION OF REMEDIES.

A paper read at the joint session of the Brainard District Medical Society and the Illinois Central District Medical Society, at Springfield, Ill., Oct., 13-11, 1892.

BY J. J. CONNER, M.D.,

MEMBER OF AMERICAN MEDICAL ASSOCIATION; MEMBER OF MISSISSIPPI VALLEY MEDICAL SOCIETY; MEMBER OF ILLINOIS CENTRAL DISTRICT MEDICAL SOCIETY; SECRETARY U. S. PENSION EXAMINING BOARD, PANA, ILL.

1. The lancet; 2. Veratrum viride; 3. Opium; 4. Coal tar derivatives; 5. Ergot; 6. Heat (poultices) 7. Cold; 8. Quinine; 9. Ammonia; 10. Calomel.

Mr. President and Gentlemen:—In presenting this subject to this Society it is not my purpose to traverse much of the field of materia medica, nor to notice many remedies, but to confine myself to a very few.

And in order to get a better understanding of the subject, I thought it best to choose some well known disease to base our study of remedies upon. I have therefore chosen pneumonia as a type of disease suitable for our purpose. As to whether or not pneumonia be a specific disease, having a certain definite course to run, and depending upon a particular microbe for its cause, or merely a local inflammation depending solely upon local causes, I shall not stop to discuss. I will say this, however, in the language of that Nestor of western medicine, N. S. Davis, "that the same process of reasoning that has caused many to call it (pneumonia) a general febrile disease, would equally assign all acute inflammations of important structures or organs to the same class." Neither shall I consider in detail the pathology of pneumonia, which, I doubt not, is as well understood by my hearers as by myself. I believe that we have in pneumonia—call it if you please, either a general febrile disease or a purely local manifestation—and in inflammation, precisely the same phenomena. In them both we have "a morbid process or alteration in a part in which there is perversion of nerve action, a change in the calibre of the arterioles, capillaries and veins; an increase in quantity and a change in the quality and motion of the blood, and in the conditions and relations of the elements of the tissues; reducing them to a more embryonic state, resulting in various kinds of metamorphoses. There is a tendency to stasis of the blood, effusion of liquor sanguinis and leucocytes through the coats of the distended vessels; and of the red corpuscles by the rupture of their coats. There is generally a tendency to the proliferation of tissue cells and to the formation of new products, viz., lymph, pus and false membrane, and sometimes to the destruction of tissue. There is perversion of the function of the organ involved, and this process is generally attended with heat, pain, redness and swelling, and by a more or less febrile disturbance of the general system." I wish particularly to call your attention to two conditions which I believe to be *the sources* of danger to which a patient laboring with pneumonia is subject. I refer to the engorgement of the right side of the heart and to the distended condition of the pulmonary vessels of the lobes of the unaffected portion of the lungs. Of course, as will be noted further on, another danger accompanies or follows the great dilatation of the vessels, viz., the paralysis of the vaso-motor nerves. As is well understood, the heart, in pneumonia, has an increased amount of work thrown upon it. The affected lobes are no longer capable of allowing a circulating current of blood passing through them, but there is a stasis of the blood and consolidation of the inflammatory products which have been thrown off during the process. Now this being so, the heart is obliged to force the same amount of blood through the unimpaired lung tissue in a certain given time as it did while all the lung substance was healthy. The unimpaired lung tissue can oxygenize only a given amount of blood in a certain time, but now all the blood must be renovated as fast and as perfectly by one lung, or by two or three lobes as it was by both lungs or all five lobes before the pneumonia began.

Now, what are the indications for treatment here? Evidently to withdraw the force of the increased circulation from the distended blood vessels in the yet unimpaired lung tissue, and to reduce the amount of work of the heart, thereby preventing distension of the capillaries and paralysis of the vaso-motor nerves, and to maintain the reserve force of the cardiac muscle, and promote resolution in the inflamed lung. If we do not relieve the pressure in the unimpaired lung tissue there will be extension of the pneumonia, because a part of the phenomena of inflammation is an increased amount of blood, in a part accompanied with rapidity of motion of the blood current. This increased blood supply and rapidity of motion in the yet unimpaired lung tissue is what leads on to inflammation of that portion which is still able to do all that it was accustomed to do, but if pushed to the extreme limit, will become itself involved in the morbid process and incapable of doing its usual amount of work. This extra blood supply to a lung yet unimpaired, will, if not soon corrected, so increase the calibre of the capillaries and arterioles that the vaso-motor nerves supplying the muscular coats of these vessels will become paralyzed, rupture of the walls of these vessels will occur and the whole lung tissue will be involved in the pneumonic process.

If we had to deal with two or more reservoirs which were supplied by a large and sufficient water-course for all proper demands upon them, and if by some mishap one or more of these reservoirs became disabled, and all the water was run into one of these reservoirs we would most certainly try to turn a part of the water in another direction, or shut off a portion of the water for fear of bursting the still unimpaired reservoir. If we for want of time or material failed in our endeavor to turn aside the rushing water, it would be necessary to tap at a certain, safe, and convenient place, the sound reservoir and relieve the undue pressure for fear the increased amount of force put upon the walls or embankments would cause them to give way. If we relieved the pressure in time we might be able to save the structure, and when the flood was over and the pressure taken off, the impaired reservoir might be repaired. So with the lungs in the storm and flood of pneumonia, we can, if the onset is not too sudden and great, cut off or relieve the pressure of the lungs by appropriate medicines and remedies, if we are given time, but if time is not given for our medicines to act, we can withdraw a portion of the blood from the turgid lungs and relieve the pressure by tapping with the lancet. The lancet is peculiarly applicable in cases of what the French are wont to call, "cerebral pneumonia," and in severe forms of pleuro-pneumonia. I have used the lancet in only a few cases, and in no case that I have used it have I regretted it; but in several cases where I did not have the courage to use it, or where such strong objections were urged against it, that I deferred to them, I have been exceedingly sorry for it afterwards. In using the lancet I bleed for effect and not for quantity.

Case 1.—F. L., male, German-American, 20 years of age. While fox hunting one night sat down upon a log to rest, being at the time wet with perspiration, although the ground was frozen and partly covered with snow. Twenty-four hours afterward, on the morning of March 13, 1881, I was called to see him by his father. As I drove to his home about three miles in the country, I made up my mind to bleed him, as I knew he was a strong vigorous young man. I had recently been reading in the *Medical and Surgical Reporter*, Dr. Hiram Corson's views on bleeding in pneumonia. I had pictured in my mind a flushed face, dry skin and bounding pulse as what I should find when I got to my patient. Judge of my surprise and great disappointment when I found a pale face, moist skin, and what I now call a clogged or obstructed pulse, but which I then thought was a weak one. I was afraid to bleed him in the condition he was in, as I was a comparative stranger in that neighborhood, which had been dominated by irregulars and eclectics. He was in so grave a condition that I said to myself "if I bleed this patient and he dies it will be said that I killed him. I will therefore treat him on general principles and if he dies I shall not be blamed for his death." He steadily grew worse until the fourth morning, when he was raising a mouthful of very thin, bloody fluid almost every breath. I saw him again that night about 10 o'clock and believed he would die the next day. On the next day, being the fifth morning from my first visit, or sixth of his illness, I found him enormously improved. I saw upon entering his room, that a great change for the better had taken place, and I tell you I was frightened. I thought another doctor had been called in. I found on inquiry that at about 5 o'clock that morning the change had taken place. At that time, during a violent spell of coughing, his nose began to bleed and had bled fully a pint in a rapid stream. Nature, not being such a coward as I had been, was the doctor that had been called in, and had bled him copiously and had cured him. But I got the credit of it. This experience taught me a lesson which I shall never forget, and gave me courage.

Case 2.—Peter C., aged about 27; had been attending along with his friends and relatives, a protracted meeting during the month of March, 1884. I was called to see him on the 16th day of the month. One of his relatives had just been buried a few days before who had died of pneumonia after an illness of about one week. This relative had lived only about forty rods from my patient's home, and my patient attended him in his late sickness. Two doctors had attended him in his illness, but they could not save him. In a consultation they had said they believed bleeding would be beneficial, but neither one dared bleed him. Peter had been sick about 36 hours when I saw him first. He was in awful distress with pleuro-pneumonia. He was sitting up in bed, being unable to lie down, cramped nearly double, and drawn to the right side holding it tightly with his arm. His skin was more like a frog's than a human's. It was cold, clammy and purplish. His eyes were bloodshot and staring. He was crying incessantly, "Oh! Oh! Oh!! my side! Oh! my head!" Nothing but grunt, grunt, grunt, and hollowing with his head and side. He said, "If you can give me anything, doctor, that will make me easy I want it quick, because I can't stand this pain any longer." I said, "Will you let me bleed you?" He replied, "I never was bled, but if it will ease me I will do anything." I told him that it would give instant and permanent relief. His skin was so pinched and veins so small that the blood would not run, and I ordered a pan of hot water to bathe the arm in. I then bled him until the perspiration stood on his brow and he got dizzy. I laid him down and he fell into a sleep for a few minutes. He soon aroused and some one said, "Pete, what do you wish?" He said, "I have not eaten anything for a day and a night, but if you will give me a square meal I will be all right." I saw him twice after that and discharged him cured. He has told me many times since that I saved his life by bleeding him. He said that medicine would have been too slow to have saved him.

In early stages of pneumonia of moderate intensity I rely on veratrum viride as my sheet anchor. It will do good in all cases of pneumonia when seen early. In its action it is more like bleeding than any other drug that I am acquainted with. It is said to "bleed the patient into himself." That is, it dilates all the capillaries and small veins which are contracted over the entire body—especially in the skin and near the surface, and relieves the internal pressure. It acts, I believe, directly upon the pneumogastric nerve, inhibiting or putting a break upon the heart, slowing its action, and also upon the great sympathetic nerve which governs the calibre of the blood vessels, the arterioles and capillaries especially.

In the beginning of a mild case of pneumonia I believe it possible to abort it by a judicious dose of opium or morphia. The opium acts by relieving pain thereby giving rest and quietude to the organism. Nature here steps in and finishes the job.

Some of the synthetic coal-tar derivatives will do the same thing, and partly in the same way. They act also upon the heat centre of the brain. It is admitted, I believe, that there is a "heat centre" governing the temperature of the body.

Ergot is said to act beneficially in pneumonia by contracting the vessels in the affected lungs, driving the blood out where it is not needed and distributing it to the general system. I have tried it only in a couple of cases. The theory of it acting in this way credits the drug with having a little too much discriminating power. By its advocates it is claimed to have what may be called intelligence enough to act only on the muscular fibre of the blood vessels of an inflamed lung, leaving untouched all the other muscular coats of the blood vessels of the system. Will it do it?

Poultices are said to act by warming the skin which relaxes the surface blood vessels, which become filled with blood, thereby drawing it off the lungs. How about the application of cold to the chest in pneumonia? How does cold relieve the pressure of the lungs? How can cold affect the vessels in the lungs when they are protected by the skin, fat, muscles, bones, fascia and pleuræ? Is it not done by depressing the heart? A better place for it then would be at the back of the head and nape of the neck in the shape of an ice bag.

Who does not give quinine in pneumonia, especially here in Illinois, but who can say why he gives it? If there is congestion of the lungs due to malarial poisoning and we have to deal with what may be called a "congestive chill," like the old practitioners used to talk so much about, all well and good, but many of us do not believe in "congestive chills" any more. Quinine acts directly upon the blood and heart. It kills the malarial parasite of the red blood corpuscle, the protozoa of Zavaran, which he discovered in 1880, and since confirmed by Osler in America and by several others. It acts upon the heart, reducing the number of beats and thereby taking the force off the lungs. It dilates the blood vessels, too, and acts also upon the heat centre of the brain. It will inhibit the heart's action in animals even after the vagi are cut. If it acts upon the heart and blood vessels as noted above, it will do good in pneumonia by draining the blood from the lungs, As quinine is a deadly weapon to the red blood corpuscle parasite, it may be that it does its good work in pneumonia by killing the diplococcus pneumoniæ of Fränkel. To be of any utility, it must be given in large doses, at least as much as 30, 40 or 60 grains 24 hours. I am apt to begin about midnight, as the temperature is nearly always lower at that time than any other, and give what quinine I wish my patient to have for the day in the succeeding 12 hours. I think it always does good when administered in this way. I think it beneficial to begin the treatment of pneumonia with a mercurial cathartic. The mercury does good in two ways, viz.: It unloads the prima viæ as well as anything else, besides it prevents the formation of fibrin and helps the ammonia salts to dissolve it after it is formed. The calomel is a good diuretic, too.

Gentlemen, I thank you.

102 Second Street, Pana, Ill.

MEMORANDA, PRACTICAL AND SUGGESTIVE.

Read at the Annual Meeting of the New York State Medical Association, November, 1892.

BY H. D. DIDAMA, M.D.,
OF SYRACUSE, N. Y.

EARLY ASPIRATION IN PLEURITIS.

In many instances pleuritis, especially the dry kind, sometimes the moist—the quantity of effusion being small—gets well with little or no treatment.

In other cases, where the attack is more severe, recovery also occurs under the use of cathartics, diuretics, sudorifics and blisters, with or without total abstinence from water or other beverage. The illness—as is well known—is apt to be prolonged; the recovery is often incomplete, and the convalescence tedious and discouraging.

Furthermore, in a large percentage of cases, the therapeutic management just indicated fails entirely to secure a favorable termination. So that the thoughtful medical attendant is sometimes perplexed to determine whether the unsatisfactory course is due wholly to the malignancy of the disease, or in part to the imperfection of the treatment.

The consensus of modern medical opinion, as expressed in books, is that after giving the remedies a fair opportunity and a reasonably generous time to secure the absorption of the pleural effusion, if the desired object is not accomplished, or if the amount of transudation becomes rapidly so great as to imperil the life of the patient, then paracentesis should be cautiously, but to a moderate extent only, performed.

The limit of this probationary period, and the danger-symptoms and signs which should be manifest before instrumental interference is justifiable, are variously set forth by different authors. Ten days to four or more weeks if the flatness on percussion does not extend well above the nipple, and if dyspnœa is not of marked severity, would fairly cover the extreme time proposed by conservative experience for waiting and watching.

For several years a minority of physicians, including the writer, have pursued a different course, with more satisfactory results. We do not regard active catharsis, diuresis or diaphoresis as an essential or important part of the treatment. Anodynes and strapping while the pain is severe; tonics, as quinine, iron and strychnine, if the patient—as *he* often and *she* usually—*is in a weak condition; and then* when with mitigation of pain and some subsidence of fever, percussion shows that fluid is present, even if the amount does not exceed an estimated half pint, aspiration is performed.

The diagnosis is verified, and the depth of the trocar puncture determined, by the hypodermic needle. Cleanliness of skin and instruments is secured. The operation at this early period is done while the patient is in a sitting posture. No effort is made to leave a portion of the effusion to be removed by absorbents.

As a rule, which has scarcely an exception in the practice of the writer, a repetition of the operation is not needed. The lung expands, normal respiratory sounds reappear, and the friction fremitus returns with exaggerated distinctness. More or less pain or discomfort is felt in the affected side, but convalescence is rapid and unattended by great prostration, and the recovery is complete.

The experience of the writer has been reasonably extensive. He has had at least forty original cases where he has performed aspiration early; and the outcome has been such that he has no inclination to resort to any other treatment now known to him.

He has been called to a considerable number of cases where a diagnosis of hepatized lung, or enlarged liver, or malign tumors had been made, and also in consultation to several cases where the diagnosis was correct and early, and where the most vigorous antiphlogistic and eliminative treatment had been pursued from the outset. In these cases—and in these only—has he found the cautions laid down by the authorities important.

In some instances the lung, crowded or retracted to the upper part of the chest, had become imprisoned by adhesions, and even carnified, so that it could not expand, while the heart was pushed or drawn over, so that its pulsations were palpable and visible to the right of the sternum.

Only a portion of the fluid could be removed without exciting violent fits of coughing, and not infrequently, after a few days, a repetition of the operation was demanded.

In a few instances—where some of the patients were young and previously healthy—pyothorax was present, apparently because an early operation had not been performed owing to reliance on authorized medication, or because a faulty diagnosis had been made.

The supporting and alleviating treatment of pleuritis, combined with early thoracentesis, seems to possess these positive and negative advantages: It is easily and safely done; it does not add to the local inflammation, but actually relieves and shortens it; it is not debilitating; it removes in a few minutes a quantity of fluid which could not be removed through the skin, kidneys and bowels in many hours, days or even weeks, and it does all this without causing weakness and slow recovery; it prevents the carnification of the lung and those tender adhesions which in late aspirations eventuate in deformity of the chest, and hemorrhage into the pleural cavity; it prevents congestion of the lung on the unaffected side, and injurious dilatation of the right ventricle; it probably secures exemption from empyema in many cases; and if it be true (as some active writers vehemently claim), that every case of pleuritis is tubercular, then this treatment, like the prompt removal of the fluid in tubercular ascites, is decidedly the most efficacious in preventing or arresting general bacillary infection.

In short, it averts death, and most safely, easily, promptly, *permanently cures the patient.*

SOCIETY PROCEEDINGS.

The American Public Health Association

Held its recent annual meeting in the City of Mexico. We are pleased to be able to give our readers the following:

Monday, November 28.

The general program prepared by the local committee o arrangements is given as under:

9 a.m.—Visit to the Mordos Hospital, at San Juan de Dios

Visit to the San Andres Hospital, on San Andres street.

Visit to the Cathedral square of the Constitution.

Visit to the Home for Foundlings on Second Merced street.

Visit to the Disinfection Department and Jourez Hospita at San Pablo.

3. p.m.—Visit to the School of Medicine, corner Doming and Perpetua streets.

Visit to the Normal School for lady professors, Sta. Catalina street.

Visit to the Law School, Encarmacion street.

Visit to the Normal School for male professors, Cerrada o Sta Teresa street.

Visit to the Conservatory of Music, at the University.

Visit to the Installation of Pumps, at San Lazaro.

At evening more music in the court of Iturbide Hotel This being the place of rendesvous,everybody(substantially met each other here from twice to a half dozen times daily so we all enjoyed the national airs of the various countrie represented at the meeting as well as the other ppoular air rendered by the orchestra before retiring for the night.

Tuesday Morning November 29.

Pursuant to announcement and according to program th twentieth annual meeting of the A. P. H. A., convened i the Chamber of Deputies (cor. Factor and Canoa streets) i the city of Mexico, the first session being called to order a 10 o'clock by the President, Dr. Felix Formento, presidin who in a few well chosen remarks, declared that the meeting was now formally opened. His first remarks wer spoken in English. After which he duplicated the same i Spanish.

Among the things he said were: This annual mee ing promises to be the grandest and most glorious of an preceding one, up to this moment 546 applications for membership having been passed on and recommended by th Executive committee for election at this meeting. Sevent five papers have been received, and altogether this meetin in our sister republic will be a most noticeable one in th history of the epoch of this organization. (He closed amidst plaudits).

The Chamber of Deputies (cámara de diputados) is a very imposing structure built of stone and marble, contains a parquette circle, two dress circles and four balconies, besides three boxes in tiers on either side right and left to the stage. The entire chamber and boxes were beautifully embellished with many flags of the Mexican and United States Republic, Central American colors and those of Great Britain, the folds of each in numerous instances being tastefully interwoven with each other. At the Tribune, above and about the President's chair, the beautiful stars and stripes of Uncle Sam predominated, although the Mexican colors of red, white and green in satin bannerettes was conspicuous in many of the other chairs and throughout portions of the dress circles. The Mexican eagle in colors was also above the president's chair. A magnificent chandelier hung in the center of the chamber suspended by a huge cable chain from the ceiling having 250 candle lights. No ladies were present at this first morning's session, and Spanish or Mexican physicians predominated in numbers. Upon ordinary occasions the boxes, parquette chairs and dress circles are occupied by diplomates and deputies, but in this instance every seat occupied contained not only a deputy or diplomat but a scientist in hygiene. In the parquette as elsewhere, it contained nice cane bottom chairs. portable. A beautiful moquette carpet, rich in design covered the floor, and throughout the entire building a great deal of beauty and taste was displayed, besides containing a great deal of gilt and rich moldings. On either side of the foyer were a number of exceedingly tastefully arranged dressing rooms, etc. In the chamber 1,000 persons can easily be seated. It was built in 1860 at a cost of $500,000.

The President was followed by Rev. J. W. Butler, D.D., in an eloquent and affecting prayer in English.

Chairman Liceaga of the local Committee of Arrangements made several announcements in the Spanish language, after which he stated in substance, translated, that he hoped any imperfections that might creep in in the program, entertainments or otherwise would be excusable, and if we did not get all we hoped or wished for, to call for it, as the committee and citizens would do everything willingly to make our guests welcome and feel at home.

Dr. Watson, the Secretary, then announced on behalf of the Executive Committee that 546 applications which he held in his hand were recommended for membership as follows: 189 outside the Federal District of Mexico, 141 within the Federal District of Mexico, 216 from the United States and Dominion of Canada.

A motion which was made empowering the Secretary to cast the unanimous vote of the Association for the names recommended without reading them, prevailed, and the vote was so ordered and declared a valid one.

Dr. Formento arose and proposed the name of President Profiro Diaz for honorary membership. The same being seconded was unanimously carried amidst vociferous applause.

The first paper read was entitled: "Influence of Climate on the Progress and Severity of Pulmonary Tuberculosis in the United States of Mexico, and Practical Consequences that are Inferred." by Dr. A. J. Carbajal, of the City of Mexico, the author reciting an experience of twenty-three years in civil and two years of hospital practice. His theme was handled in a most satisfactory manner. The paper was read in Spanish.

The second paper read was by Dr. R. C. Kedzie, of Lansing, Mich., who selected for its title "The Ground of Safety." The author illustrated his remarks by essaying to blow air through leather, India rubber, plaster and cylinders of oak wood each twelve inches in length and two inches in diameter, before an ignited candle. He demonstrated that he could blow air readily through a six inch cylinder of plaster. To blow through a paper wall—it was dead and it does not breathe; in other words, it is a strangled wall. A calcimined wall laid on with glue, there is a very slight breath. A dry plastered wall—air will pass through it. A wet plastered wall—air is drowned or strangled; water stops soil breath.

Third paper, a short one, presented by Dr. W. A. Haskell, of Alton, Ill., read by Dr. *Gihon*, entitled, "Medical Demography."

The fourth paper presented was by Dr. Domingo Orvanos, of the City of Mexico, and first Vice-President of the Association. The author, who read in Spanish, chose for the title of his paper, "Climate of the City of Mexico." This paper was discussed at length in Spanish by Dr. Otero, of Mexico.

The Association then adjourned until 3 P.M. to meet in the main hall of the National Preparatory (High) School.

The scientific business during the afternoon of the first day, at the National Preparatory School, was transacted with Dr. Formento, the President, in the chair, and was well attended.

The first paper read was by Dr. Rafael Lavista, of the Federal District of Mexico, whose subject was, "General Considerations upon the Public Health," read in Spanish. It was a brief paper and its author elicited considerable applause at the close of reading it.

Dr. W. M. Yandell, of El Paso, read the second paper, which was a brief one, on "Contagious Diseases on the Rio Grande Border." The paper was statistical in nature, timely and its author was warmly applauded.

A paper showing a new method of quantitative chemical analysis to obtain nitrogen from organic matter, based on the transformation of nitrogen into ammonia, was read. The process was by the Mexican chemists Alexander Noibey and Victor Lucioy Ortego.

The next paper read was by Dr. William T. Corlett, of Cleveland, O., "On Some of the Infectious Diseases."

After the reading of the above paper Dr. Liceaga introduced the subject, "Against the Marriage of Persons Infected with Tuberculosis." He argued that phthisis was a contagious disease and cited a number of cases to prove his statements. Considerable discussion ensued. The tendency and preponderance of opinion was to agree with Dr. Liceaga.

An adjournment was then taken to meet in the National Theatre at 8 P.M. to attend the solemn inaugural session. This is a beautiful building and was filled from pit to dome by the best citizens of the Republic (ladies and gentlemen) in evening dress. Archbishop Alarcon invoked the Divine blessing at this formal solemn opening, and Dr. Liceaga delivered the address of welcome. During the evening a superb orchestra of sixty pieces under the directorship of Senor Jose Rivas, Director del Conservatoire National de Musical, discoursed fine music, among the numbers being the Star Spangled Banner, God Save the Queen, Mexican National Hymn, etc.

The limited space of THE JOURNAL precludes the publication *in extenso* of the very able addresses delivered at the formal solemn inauguration this (Tuesday) evening by Dr. Liceaga, Chairman of the Local Committee of Arrangements, and Dr. Formento. President of the Association. The following extracts of each are herewith given. Dr. Eduardo Liceaga closed his magnificent Address of Welcome in the following words:

"And what have our visitors come to do in our midst? They have come to impart to us their own faith, to instruct us in their method of working, to spread new ideas, to concert with us a mutual plan of defense against the propagation of such diseases as arise among us, to see what means Nature employs to enable us to breathe at this immense altitude, to observe how we build our dwellings in a climate in which artificial heat is not required, to admire the purity of our atmosphere, the transparency of our light, the radiance of our sun, to examine the modifications produced by the meteorological conditions of this altitude, within the tropics, on the mode of existence of animated beings.

"As for ourselves, we welcome them with open arms. We purpose to show them our hospitals, far inferior, alas, to the splendid monuments which they have reared in the name of charity; to explain in what manner the Government extends protection to foundlings, to ailing children, to orphans, how it imparts to them a knowledge of the mechanical arts, how it reclaims the erring, and how many of these institutes are organized on a military footing. We shall conduct our guests through the establishments where education is furnished to the teachers, male and female, whose duty it will be to spread the benefits of elementary knowledge, through our Preparatory Professional School, through our Schools of Medicine, Jurisprudence, Music, and Fine Arts, through our National Medical Institute—not on account of the intrinsic excellence of these establishments, nor because we imagine that they can endure comparison with the superb foundations which private munificence has reared in your own countries—but because we believe that perchance you may take an interest in beholding these evidences of the moral and intellectual development of this people, so torn by political convulsions which attack nations in their infancy and adolescence just as disease attacks and exhausts the physical and mental constitution of man in boyhood and early youth.

"We shall show you, too, the works recently undertaken to secure an improved water-supply. At your last meeting one of our sanitary engineers explained to you the project for a new sewerage system for the city, to supersede the present very defective one, and now you are about to see the provisional works undertaken for the purpose of improving the flow of the sewers until such time as the new scheme can be carried out in its entirety. We shall enable you to view, and as hygienists you will be interested in viewing, one of the most gigantic works ever undertaken for the sanitation of any city—the drainage of the Valley of Mexico. Finally, we shall conduct you through the suburbs of the city and spread before your eyes a view of this broad valley from the historical hill of Chapultepec.

"And as for you, esteemed fellow-countrymen, who have also left home and business and come hither from afar to recount your experience of the dreaded yellow fever, your speeches will inform us whether that scourge is produced spontaneously among you or whether it is imported, and if so, in what way, and what steps you have taken to liberate the coasts from its ravages. Others among you will tell us the places where malaria prevails and what has been done for their sanitation, the regions in which tuberculosis is unknown or its ravages are less violent than on our coasts, the towns which are free from diphtheria, those others in which it rages, the measures which you recommend to prevent the spread of typhus, the method by which your cities are supplied with water, and all other matters of interest to hygienists.

"Little has been done as yet towards the sanitation of our cities, but this is a truth which we need not be ashamed to confess, for we are a young people desirous of understanding thoroughly the evils under which we labor before seeking a remedy. Our Governments have given us good sanitary laws and it remains for us to devote our intelligence, our energy and our zeal to the service of our countrymen and the fulfilment of those laws, thus contributing to the noble ends of the American Association of Public Health, which has accomplished such splendid results in the United States and Canada, and which will, we trust, accomplish the same results here.

"Gentlemen, receive the thanks which I offer you in the name of my country for having selected this city as the scene of your annual meeting.

"Gentlemen, I bid you welcome."

Dr. Felix Formento concluded his lengthy address as follows:

"In my opening remarks, were mentioned the causes which created particular interest in the present reunion; a spirit of justice induces me to recall here the two factors which have mostly contributed to its success:

"Shortly after our last meeting in Kansas City, our worthy Secretary undertook, in the interest of our Association, a long and fatiguing journey to the remotest regions of this immense country, to Cuba and Central America. Its principal object was to excite the interest of the people and of the different governments in sanitary matters and to obtain their participation in this meeting. To that effect Dr. Irving A. Watson was commissioned "Health Ambassador" to Mexico, Cuba and Central America. For the first time, perhaps, was such a mission confided to any one. No ambassador of kings or monarchs ever received a more flattering and hearty welcome—an honor rendered to the personal merit of the man as well as to the representative of this great international organization. His mission was a complete success.

"The Chairman of the Local Committee of Arrangements plays a no less important part in the happy results of our meetings. No better selection could have been made than that of our eminent and distinguished chairman, Dr. Eduardo Liceaga. To the high official position he occupies, to the legitmate influence he commands, to his scientific attainments and social standing in this community, the success of the Congress is mainly due.

"This double debt to our Secretary and to our Chairman of the Local Committee of Arrangements, is cordially acknowledged and I take pleasure in tendering them the thanks of the Assembly and the assurance of my personal gratitude.

"Let us congratulate ourselves, gentlemen, upon our acceptance of the pressing invitation of the Mexican Government to hold our meeting in this city. The intelligent transfer of the scene of our debates, far beyond our boundaries, to the capital of our friends and neighbors, is the first step to the scientific unification of the whole American Continent. This is the first International Health Congress held on this side of the Atlantic. As such it is our duty to unravel the problem of yellow fever, which is the only obstacle to the much desired commercial, social and intellectual intercourse between our respective countries and nations. Yellow fever is the curse and drawback of America's southern climes. If this meeting could successfully devise the means of stamping it out forever from all parts of the Continent, it would richly deserve the blessings of future generations.

"In another point of view, this meeting deserves our reciprocal congratulations. We need only to meet in conference and immediately a bond of friendship is sealed, not merely between scientists, but between the two nations.

"In addition, what an opportunity, never to be forgotten, of seeing, of admiring Mexico in all her glory! Of being able to witness the grandeur, the prosperity of this land of the Montezumas under its progressive republican form of government, its modern resources, to contemplate its bold railways and viaducts, suspended in mid air, in their vertiginous ascent and descent of gigantic mountains, its beautiful valleys, torrents and streams, its majestic scenery, its thriving towns and cities, rendered rich by local industries, its mines and its forests, its palaces, cathedrals, schools, and museums—the whole thing brought out in relief by the vestiges of its immortal past, a double civilization in striking contrast!

"Should we leave unmentioned its delightful climate, its blue sky, its wonderful fruits and beautiful flowers?

"But above all stand the noted courtesy, the exquisite refinement of its inhabitants, who have made us at home and filled our hearts with everlasting gratitude!

"This day will be inscribed in gold letters in the Annals of the Association, and I hereby express the sentiment of the assemblage, when I exclaim from the bottom of my heart: 'Viva Mexico!'"

To resume our personal reminiscences. This afternoon among the notable places visited were the National Palace, where we were received with honors by a number of army officers who devoted themselves to showing us very many sights in the various apartments throughout the building, among which was President Diaz's state chair, the president's rooms, portraits of Inarez, Hidalgo, Washington and Maximillian and many other historical personages in the Ambassador's hall. We were also escorted through the Government departments, other public offices, etc., and before leaving were presented to General Pradillo, the Governor.

We also visited the National Museum this afternoon and saw many curious Aztec antiquites, picture writing, Montezuma's shield, the statue of Huitzilopochtli. the God of War, the Calendar stone, Tula Monoliths, goddess of water, Palemke cross, Chacmol, and the Sacrificial stone, oil portraits of viceroys and of Cortez, Maxmillian's gala coach, and his silver service. We also visited the Natural History and Mineralological departments that contain an innumerable variety of skeletons—the taxidermists' art, etc.

The social program for this (Tuesday) day as arranged by the Social Committee was as follows:

At 8 A.M., visit to the Beneficiary Offices and Central Pharmacy on Xicotencalt street; visit to the Mining Schools on San Andreas street.

At 1 P.M., visit to the Arts and Trades School for men, Estampa of St. Lorenzo street; visit to the Preparatory School, San Ildfonso street.

From 3 to 5 P.M., session in main hall of said school.

5 P.M., visit to Central Meteorological Observatory, at the National Palace; and at 8 P.M., solemn inauguaration at the National Theatre.

(*To be concluded.*)

DOMESTIC CORRESPONDENCE.

To the Editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

It is safe to affirm that nine-tenths of the regular profession heartily agree with the views, stated by "Conservative" in his letter to THE JOURNAL of the 10th inst., as to any essential change in the code of Medical Ethics—as now recognized by the American Medical Association.

In addition to his admirable presentation of affirmative reasons for the retention of the code in question, it may be stated that every annual meeting in the history of the Association has offered an opportunity to cancel or revise the provisions of said code—and aside from recent left-handed movements having origin in a single locality and society tributary to the organization—and whose animus and spirit only tended to sustain the principle they would undermine—other than this the code has retained that freedom from disapproval due to its excellence and origin. As the declaration of cardinal principles relative to medicine, it is the analogue of that framed by Jefferson as applying to the citizen, and that upon which each are founded in theology, the "sermon on the mount." Its abrogation would be worse than suicidal, its revision—as to essentials—a dangerous experiment.

The one provision objected to by the free for all go as you please advocates, is, in the nature of events and the period which now obtains *the one* specially amenable to a more rigorous interpretation or amendation—the daily press in solid phalanx for the defense and promotion of quack advertising, methods and literature, its direct channel of finahcial sustainance, is a giant menace to honorable practice, and an increasing force for the breaking down of all distinctions between merit and fraud, ability and ignorance, honor and cunning. No such influence operates to prevent the full recognition of merit and talent by the press of legal and clerical claiments of public approval, hence public security against imposition in medicine resides in the profession, and handicapped, as stated at that, by the immense dead weight of a subsidized press. It follows that medical impostors have allies and support quite sufficient without adding the assistance of a common level consultationship with qualified practitioners. It degrades, and does not—for it cannot—elevate decent and legitimate practice, something that demands, like all worthy factors of civilized life, the most vigilant care. IOWA.

BOOK REVIEWS.

DISEASES OF THE CHEST, THROAT, AND NASAL CAVITIES including Physical Diagnosis and Diseases of the Lungs, Heart, and Aorta, Laryngology and Diseases of the Pharynx, Larynx, Nose, Thyroid Gland and Œsophagus. By E. FLETCHER INGALS, A.M., M.D., Professor of Laryngology and Practice of Medicine, Rush Medical College; Professor of Diseases of the Throat and Chest, Northwestern University Woman's Medical School; Professor of Laryngology and Rhinology, Chicago Polyclinic. etc., etc. Second edition, revised and enlarged. 240 illustrations. Octavo, 700 pages, extra muslin, price, $5.00. William Wood & Company, New York.

The second edition of this book is a gratifying improvement on the first. The author has done himself credit and added to the value of this volume in several directions. In the part devoted to the heart and lungs he does not restrict himself, as in the first edition, to the diagnosis and treatment, but has amplified his work by adding the subjects of etiology, pathology, symptomatology and prognosis. The division on nose and throat diseases has been quite largely re-written. In passing from diseases of the lungs and heart to those of the nose and throat, one cannot escape the impression that the natural dissociation of these subjects should induce the author to produce two books instead of one. This would enable him to do greater justice to his acknowledged ability by treating in detail in one volume those diseases which lie in the province of the general practitioner, and in another, those affections which the modern evolution of the science of the economy of labor has assigned to a generally recognized specialty.

Probably no one will feel more keenly than the doctor himself the embarrassing limitations imposed on this work, which, if treated with desirable fullness, would far outgrow the handsome and convenient book he has produced. The inference is naturally suggested by the regrets expressed in the prefaces to both volumes, that it is impossible for him to accord credit to many authors to whom he is indebted for material, since this feature forms not the least interesting and weighty part of such a treatise. The writings of Morrell Mackenzie afford a generous and scholarly illustration of this kind of authorship, and doctors, like lawyers, are fond of having authorities quoted.

The article on pulmonary phthisis is limited to twenty pages. The reader will wish it had been extended to double that number in Dr. Ingals' entertaining style. No room is given to tuberculin, but the details and results of the Shurley-Gibbes treatment are plainly and practically stated. Asthma, on which Hyde Salter has written a book, is given a little more than four pages. The author seems to have lost none of his enthusiasm for the galvano-cautery. The writer recently asked a specialist and professor in these diseases what galvano-cautery apparatus he employed. "Not any," was his reply. But there is a happy medium in these matters, although it may not be the patient. The doctor also retains his preference for aqueous solutions and powders in catarrhal conditions. The frequency with which patients are given cocaine preparations for home treatment is surprising when we remember its paralyzing effect on the vaso-motor nerves, sometimes producing a secondary congestion which transcends the existing pathological condition, and knowing the misery which the cocaine habit has inflicted on its victims.

In the article on "throat deafness" the theory is announced that in rarefaction of the air in the tympanic cavity "producing tension of the tympanic membrane, the chain of ossicles is put on the stretch," etc. This is somewhat at variance with the teachings of the older authorities. On page 602 there is described the appearance of the drum head in the region of the "malleolus"—probably a cerebral slip, the author having ankylosis in mind. His advice to have patients treat themselves daily by injecting vapors of iodine and eucalyptol into their middle ears with inflators is out of harmony with the teachings of the leading authorities of the day.

A commendable feature is the frequent use of comparative tables for differential diagnosis arranged in parallel columns, enabling the student to form a mental picture of the variations of similar diseases at a glance.

The publishers have maintained their high standard of excellence in the typographical art. The type is of good size, clear, with only little lapses into trying fine print, and the paper has but one fault. It is glazed sufficiently to reflect the light into the reader's eyes at night. As physicians usually have no other time for reading, it is unpardonable for publishers to inflict this eye-weakening punishment upon their best friends. The book is embellished with numerous illustrations that are generally good.

One does not need to jog his memory very violently to stir up the recollection of the time when western men thought it necessary to draw their medical inspiration from the founts of learning which, *cum gratia Dei*, blessed that part of America only that lay east of the Alleghany mountains. Since the profession of the great Northwest has irreverently dispelled this delusion, has the time not arrived when the execution of the mechanical and artistic part of our book-making can be effected in the neighborhood of the libraries and hospitals where the book material is produced? An answer to this question seems to lie in the fact that in Chicago there are 1,300 firms employing 20,000 people, sending annually more than 15,000,000 bound volumes to the book patrons of the world.

IT is said that its enemies spent $60,000 to defeat the Paddock Pure Food Bill. As it advocated patented and proprietary foods, etc., its death may not be regretted.

SELECTIONS.

THE BRAIN CENTRES OF THE EMOTIONS: ARE THERE SUCH CENTRES?—According to Spencer and Bain, those physical states which we class as feelings are inseparable from those which we class as intellectual processes. Feeling, thought and volition constitute a "trinity in unity;" they are characteristic in their several manifestations, yet so dependent among themselves that neither could subsist alone; neither will nor intellect could be present in the absence of feeling, and feeling manifested in its completeness carries with it the germ of the two others (Bain). Feeling, according to Spencer, is the primordial unit of mind, and emotions are highly complex aggregates of simple feelings.

Dr. S. V. Clevenger, in the *American Naturalist* for November, 1892, accepts and reinforces this view. The emotions have vaguely been regarded as having several centres, or a single centre. Often in physiological writings we encounter the term "emotional centre," and reasons more or less incorrect have been advanced locating this "emotional centre" at the base of the brain.

Emotionalism, Dr. Clevenger says, in a broad sense is nothing more or less than degrees of excitement. So from this standpoint it is a condition, an exaltation or depression of the nerve-centres; and hence it would be absurd to look for its centres. Joy, grief, anger, fear, jealousy, are all conditions which may engage every cell in the body at times. The fact that there may be crying and laughing centres in the medulla does not constitute that portion an emotional centre any more than we are justified in calling the leg centres in the brain-cortex, kicking centres. The laugh and cry may be purely automatic, and without reference to the emotions at all. Besides, some emotional exhibitions, such as tremblings and pallor, indicate that during emotional excitement nerve force is pretty well diffused throughout the body, and that no particular set of nerves is engaged. It would seem that in such instances there is excellent evidence of the absence of an emotional centre, and the shaken-up general nervous system can find no special outlet for the feeling.

When a rupture of a blood-vessel in the motor centres of the brain causes paralysis, and in cerebral degenerative states, such as are induced by alcoholism and senility, there is an increase of emotionalism. The patient may cry and laugh easily; but in such cases the higher control is lost, impressions are diverted from former channels in the brain to the more automatic ones lower down, but the emotionalism is the product of brain injury and is a debased condition, and hence has no centre in the brain. The fact that the brain-base at its junction with the spinal cord has laughing and crying reflex centres may warrant this area being named an emotional centre in a very limited sense; but, strictly speaking, there can be no such thing as a centre for the emotions, for laughing and crying are but two among a great number of emotional exhibitions, and they may recur unconsciously.—*Boston Medical and Surgical Journal.*

ELECTRICITY IN PELVIC TROUBLES.—On the use of electricity for pelvic troubles, Dr. Price says: "It is utterly incomprehensible how any sane man can advocate the use of electricity; it seems that it is only in such hidden regions as the pelvic that the electricians claim any resulting good from their treatment. Why not apply this all-powerful, this infallible and omnipotent curative effect of electricity to the resolution of abscesses found in the neck of strumous children? Certainly wealthy mothers would pay well, even handsome fees, to save their children from carrying through life loathsome scars. not to mention the satisfaction of the operator upon curing his patient without the deformity resulting from the formation of a cicatrix."—*National Medical Review.*

THE

Journal of the American Medical Association

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE $5.00

SINGLE COPIES. . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

No. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1271, Philadelphia, Pa., *sending him a certificate or statement that he is in good standing in his* own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for The Journal. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly Journal of the Association will be forwarded regularly.

SATURDAY, DECEMBER 24, 1892.

THE CODE OF ETHICS, CONSTITUTION AND BY-LAWS OF THE AMERICAN MEDICAL ASSOCIATION.

The Committee on Revision, of which Dr. A. M. Holton, of Brattleboro, Vermont, is chairman, is anxious to obtain as much of an expression of sentiment in relation thereto as possible; to that end correspondence is solicited from all who are interested in this subject, in order to enable the committee to frame such a revision as will represent the opinions of the majority of the members of the Association. Such correspondence may be addressed to either member of the commiteee: A. M. Holton, Brattleboro, Vermont; Leartus Connor, Detroit, Mich.; H. D. Didama, Syracuse, New York; Daniel T. Nelson, Chicago, Ill., and Benjamin Lee, Philadelphia, Pa.

RESULTS OF RESEARCHES IN BACTERIOLOGY.

The practical value of bacteriology is now questioned no longer. The invaluable services which this young science has rendered preventive medicine by placing disinfection and sanitation upon a sound basis; the immense benefit it has brought to antiseptic and aseptic surgery and obstetrics by clearly defining the exact indications for, and the most reliable methods of sterilization; the positiveness in diagnosis which the actual demonstration of the specific cause of a disease affords; and the protective inoculation with attenuated cultures against infectious diseases in the domestic animals—these are results of bacteriological researches of such practical value as to satisfy the highest expectations of the enthusiast of a few years ago.

To-day bacteriology is about to revolutionize medicine by elaborating a specific treatment of the infectious diseases.

The demonstration that pathogenic bacteria are virulent on account of their chemical products and the study of the toxines and toxalbumens of infectious diseases led to the discovery of anti-toxines in the blood of animals immune against certain diseases and these anti-toxines were found to have an unexpected antidotal power. The researches of Buchner, Martin, Hankin, Nuttall, and others paved the way for the demonstration by Ogata and Jasuhara that the injection of a drop of blood from an immune frog will protect a mouse against an ordinary fatal anthrax inoculation, and then Behring and Kitasato showed that the blood of animals immune against tetanus and diphtheria, if injected into susceptible animals, prevents fatal infection with virulent cultures of the bacilli of these diseases; suitable experiments readily showed that the toxalbumen of the tetanus bacillus is nutralized when mixed with the blood of immune animals and the next step was the isolation of the tetanus-anti-toxine by Tizzoni and Cantani and the successful treatment of actual cases of traumatic tetanus by means of tetanus-anti-toxine injections. Already six cases successfully treated by this novel and specific but absolutely scientific method have been recorded in medical literature, the first one being reported by Rudolph Schwartz.

G. and F. Klemperer then showed that the blood serum of animals artificially immune against croupous pneumonia renders susceptible animals immune and that it has a direct curative effect if injected after the development of the disease. Preliminary communications are at hand announcing the discovery of anti-toxines antidotal to tuberculosis and to rabies, and numerous ingenious experiments are constantly being made demonstrating that acquired immunity is due to the development of anti-toxines. Recently Sternberg has demonstrated by proper experiments that the blood serum of calves immune by previous attacks of vaccinia to vaccine virus contains something which neutralizes humanized or bovine lymph.

These few lines, briefly touching the main landmarks in the development of the present knowledge of the toxines and anti-toxines of infectious diseases will serve to call attention to the revolution in treatment which these researches may bring about. The work of isolating anti-toxines, of testing their specific action in neutralizing the toxic products of specific diseases both before and after the development of the disease, and the task of producing anti-toxines in amounts sufficient and suitable for practical therapeutic use, will be carried on enthusiastically and unremittingly by investigators all over the world, each believing that when bacteriology discovered the anti-toxine a new era dawned in the history of medicine—the era of specific treatment of infectious diseases.

A PROPOSED CHANGE IN THE MEDICAL COURSE OF STUDY.

One of the most serious errors in our present course of medical study, as offered in the best four year institutions, lies in the presentation of too many subjects at a time. Time was when the medical school offered six studies and had six professors. During the first year the student had anatomy, physiology and materia medica, during the second year medicine, surgery and obstetrics. In fifteen years as many new branches have come into the curriculum, and yet in many schools six or more studies are required of the student coincidently during the crowded term of each year. From an educational standpoint, this is a grave error. Not more than four different branches should be required of a student at a time. The course of lectures and laboratory work should be divided into two portions for each year. The first portion should be given during the first half of the term, the second portion during the second half.

In this way the student could go about his work without confusion and yet with sufficient variety. At the end of the half course there should be a final examination and credit should be given for the work done. The quality of the work done would be bettered by the concentration both for the teacher and the student.

The course of study might be something like the following, remembering that each branch would receive *one* hour *a day* in recitations or lectures and *two* hours *a day* in laboratory work and clinics during seventy days.

FIRST YEAR, FIRST HALF.

1. Comparative anatomy, laboratory.
2. Chemistry, recitations.
3. Physics, recitations.
4. Physiology, recitations.

FIRST YEAR, SECOND HALF.

1. Histology, laboratory.
2. Chemistry, laboratory.
3. Human anatomy, recitations.

SECOND YEAR, FIRST HALF.

4. Human anatomy, recitations.
2. Human anatomy, laboratory.
3. Histology, laboratory.
4. Elective work.

SECOND YEAR, SECOND HALF.

1. Embryology, laboratory.
2. Human anatomy, laboratory.
3. Materia medica, recitations.
4. Elective work.

THIRD YEAR, FIRST HALF.

1. Pathology, general, laboratory.
2. Medical clinics.
3. Medicine, recitations and lectures.
4. Topographical anatomy and physical diagnosis, recitations.

THIRD YEAR, SECOND HALF.

1. Pathology, special, laboratory.
2. Surgical clinics.
3. Surgery, recitations and lectures.
4. Elective work.

FOURTH YEAR, FIRST HALF.

1. Two specialties, each one-half, lectures and recitations.
2. Clinics on specialties.
3. Clinical diagnosis, laboratory.
4. Thesis work.

FOURTH YEAR, SECOND HALF.

1. Two specialties, each one-half, lectures and recitations.
2. Operative surgery, laboratory.
3. Clinics on specialties.
4. Elective work.

This rude outline is enough to show what can be done. It might be well to offer this work twice a year in the larger schools, and in that way the capacity of the best located schools could be doubled.

Four of the eight groups could be given each spring, alternating from year to year; or better still, the school could continue the year through, and sufficient elective work offered to lengthen the term to nine months, These elective courses would be a means of medical culture for the undergraduate and would furnish an opportunity for post-graduate work.

The Southern Medical College Association.

To the Editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

An editorial in your issue of December 10, 1892, in reference to the two Medical College Associations, does great injustice to the action of the Convention of the Southern Medical Colleges, which was recently called to meet and did meet, in Louisville, Ky., for the *sole purpose* of raising the standard of medical education in the South.

At a meeting of the Faculty of the Medical Departments of the University of Nashville, and Vanderbilt University, in August last, a committee was appointed to call a Convention of the Medical Colleges of the South for the purpose of raising the standard of medical education in the South. The call was made by circular letters mailed to the officers of every reputable Medical College in the South, and answers were received from all addressed (except one) warmly endorsing the movement and promising hearty coöperation.

The "sequestered" city of Louisville was named as the place of meeting, and the 16th of November last as the time for the meeting.

Every reputable medical college of the South, except one, was represented by either delegates or by letters.

Methods of instruction and requirements for matriculation, which differed in no essential particular from the plans and requirements of the American Medical College Association, except in the educational requirements, were offered and adopted.

A large majority of those in attendance, while desiring as high a grade of literary qualification as could be attained, yet opposed the requirement of more than a good, substantial English education preliminary to matriculation. This difference in the requirements of preliminary education would, in the opinion of many of those present, deter a large number of medical colleges from becoming members of the American Medical College Association, and hence it was proposed to organize a Southern Medical College Association, provided three-fourths of the Southern Medical Colleges became members of that body.

Those present at the convention entered the Association with enthusiasm, and many others have since become members by letter, and in a short while every reputable medical school of the South will become members of the Association.

There is no valid reason why a college may not consistently be a member of both Associations, as they were both organized for the same purpose, viz.: the elevation of medical education, and there is no doubt that many of the colleges of the South will become members of the American Medical College Association at an early date.

The medical colleges South have determined to raise the standard of medical education to as high a point as the American Medical College Association will, it matters not how high this point is.

Below we insert the requirements in each Association side by side:

Requirements of the American Medical College Association.

Section 1. Members of this Association shall require of all matriculates an English composition in the hand-writing of the applicant of not less than two hundred words; an examination by a Committee of the Faculty, or other lawfully constituted Board of Examiners, in higher arithmetic, algebra, elementary physics and Latin prose.

Sec. 2. Graduates or matriculates of reputable colleges, or high schools of the first grade, or normal schools established by State authority, or those who may have successfully passed the entrance examination provided by the statutes of the State of New York, shall be exempt from the requirements of Section 1.

Sec. 3. Students conditioned in one or more of the branches enumerated as requirements for matriculation shall have time until the beginning of the second year to make up such deficiences, provided, however, that students who fail in any of the required branches in this second examination shall not be admitted to a second course.

Sec. 4. Colleges granting final examination on elementary subjects to junior students shall not issue certificates of such final examination, nor shall any member of this Association confer the degree of Doctor of Medicine upon any person who has not been first examined upon all the branches of the curriculum by the faculty of the college granting the degree.

Sec. 5. Candidates for the degree of Doctor of Medicine shall have attended three courses of graded instruction, of not less than six months each, in three separate years.

Sec. 6. Students who have matriculated in any regular medical college prior to July 1, 1892, shall be exempted from these requirements.

Requirements of the Southern Medical College Association.

Requirements for Matriculation.—Every student applying for matriculation must possess the following qualifications:

He must hold a certificate as the pupil of some known reputable physician, showing his moral character and general fitness to enter upon the study of medicine.

He must possess a diploma of graduation from some literary or scientific institution of learning, or certificate from some legally constituted high school, general superintendent of State education, or superintendent of some county board of public education, attesting the fact that he is possessed of at least the educational attainments required of second-grade teachers of public schools. Provided, however, that, if a student so applying is unable to furnish the above and foregoing evidence of literary qualifications, he may be permitted to matriculate and receive medical instruction as other students, and qualify himself in the required literary departments, and stand his required examination as above specified, prior to offering himself for a second course of lectures.

The foregoing diploma or certificate of educational qualifications, attested by the dean of the medical college attended, together with a set of tickets showing that the holder has attended one full course of medical lectures, shall be essential to attendance upon a second course of lectures in any college belonging to this Association.

Branches of Medical Science to be Included in Course of Instruction.—Anatomy, physiology, chemistry, materia medica and therapeutics, theory and practice of medicine, pathology, surgery, obstetrics and gynecology, hygiene, medical jurisprudence (forensic medicine), and special laboratory work as hereinafter provided.

Qualifications for Graduation.—Candidates for graduation, in addition to the usual requirements of medical colleges, must have attended three courses of lectures of not less than six months each, in three separate years; must have dissected in two courses, and attended two courses of clinical or hospital instruction; and must have attended one course in each of the special laboratory departments, to-wit: 1. Histology and Bacteriology; 2. Chemistry; 3. Operative Surgery.

These requirements shall not apply to any student who has received a course of medical lectures prior to September 1, 1893.

Yours, etc.,
W. T. Briggs.
G. C. Savage.

HEALTH DEPARTMENT.

No. 301 Mott St.
New York, December 13, 1892.

Hon. Chas. G. Wilson,
President Health Department.

Sir:—I have the honor to submit the following report of the pathological and bacteriological work of this Department during the outbreak of cholera in this city which occurred during September of the present year.

In this work I secured the coöperation of Dr. Edward K. Dunham of the Carnegie laboratory, who has had large experience in biological work connected with Asiatic cholera at the Hygienic Institute in Berlin, and I desire to acknowledge here my great indebtedness to him for biological investigations in this connection.

As bearing upon what is to follow, I desire to direct attention to certain features in the diagnosis of Asiatic cholera. It is admitted by all clinicians of experience that a differential diagnosis between sporadic and Asiatic cholera cannot be made on the clinical history alone. In the absence of an epidemic of Asiatic cholera, or the proof of direct exposure to Asiatic cholera, no one is justified on the clinical history alone in making a diagnosis of this disease. In the beginning of an epidemic of Asiatic cholera the first cases are always doubtful cases, and often their true nature is not recognized until the disease has become epidemic.

It is not very unusual to see cases of sporadic cholera presenting the exact clinical picture which is presented in the severest types of epidemic cholera, and on the other hand, it has often been the testimony of all observers in the recent epidemic in Europe that frequently epidemic cholera takes such a mild form, and resembles so slightly the severest types of the disease, that any suspicion as to its nature would not be aroused, were it not for the existence of the epidemic or the results of biological examinations.

In 1884 the German Government sent a commission, of which Robert Koch was the head, to Italy, Egypt and India, to study Asiatic cholera, and to determine if possible its cause. A peculiar organism was found in the intestinal contents and in the intestinal discharges of cases of cholera, occurring in the epidemics in Italy and Egypt, and also in India, where the disease is endemic. This organism, because of its curved form, was originally called the cholera comma bacillus, but is more properly called the cholera spirillum. Koch showed by his investigation that this organism was present almost in pure culture in the intestinal contents and in the intestinal discharges from cholera patients during the height of the disease, that it bore a definite relation to the course of the disease, appearing with severe symptoms and disappearing as severer manifestations passed away; that it was never found in any other disease, and that it might be cultivated in various substances outside of the living body.

Several other microörganisms were afterward described by other observers (one of which occurs in the human mouth, another in a form of sporadic cholera, a third in stale cheese), which resemble very closely in their morphological appearance the cholera spirillum. But when all the biological characteristics of these various organisms are considered, they can with great certainty and ease be differentiated from each other.

It is now admitted by all prominent bacteriologists of the world, so far as I am aware, that the spirillum of Koch is absolutely characteristic and pathognomonic of Asiatic cholera, and that its biological characteristics differentiate it with certainty from all other microörganisms. When this organism is found, the diagnosis does not remain longer a question of opinion, but becomes a scientific fact, regarding which there can be among competent observers no difference of opinion. To determine the nature of the organisms, however, it is necessary to not merely examine microscopically the intestinal contents or discharges, but to isolate and cultivate the spirillum in suitable media, and to study its characteristics. This process requires for the identification of the cholera spirillum in different cases, according to the conditions, from two to four days.

The second occasion in the history of cholera epidemics in any part of the world in which biological examinations were practically resorted to for the diagnosis and exclusion of this disease, was in the cholera epidemic, which occurred at the York Quarantine Station in 1887. Dr. William M. Smith, then Health officer, brought to me culture tubes inoculated from the intestinal contents of a child who had died with what had apparently been cholera morbus. The vessel from which the child had been removed, was supposed to be free from infection, although she had sailed from an infected port. Dr. Smith requested an opinion as to whether the disease which caused death was sporadic or epidemic cholera, and offered to hold the vessel until the question was determined. The examination by three independent observers (Dr. Prudden, Dr. Weeks and myself) showed at the end of forty-eight hours that the disease was Asiatic cholera. Four hundred immigrants were then removed from the vessel, and several days later a number of other cases occurred among them. Asiatic cholera was then only excluded from New York City by reason of the biological examinations.

In view of the above facts, the importance of biological examinations in the diagnosis of Asiatic cholera is, it seems to me, at once apparent.

The first case referred to me for investigation was that of a laborer, Chas. McAvoy, age 32, who died on September 7, after an illness of about thirty-six hours' duration. He had suffered from severe watery diarrhœa and vomiting, accompanied by persistent cramps in the abdomen and limbs,—collapse and death followed. This case was reported to the Health Department by physicians in attendance as probably one of Asiatic cholera.

At the autopsy, such lesions as may be found in cases of death from both sporadic and epidemic cholera were present. In the absence of any evidence of exposure to infection from epidemic cholera, and inasmuch as the microscopical examination of the intestinal contents was negative, and the anatomical lesions found in both sporadic and epidemic cholera may be so nearly identical as to make a differentiation on this ground impossible, the conclusion was reached, provisionally at least, that this was a case of sporadic cholera, and the cause of death was so returned to the Health department.

A biological examination, however, was immediately begun, and on the 10th of September the investigation had proceeded to such extent that it was considered certain that it was a case of epidemic cholera. Realizing very fully, however, how many and what important interests were at stake, an official report was not presented to the Health department until several days later, after the diagnosis had been confirmed by Dr. T. Mitchell Prudden, consulting physician to the Health department in the Division of Pathology, Bacteriology and Disinfection. A report was then forwarded to the department, correcting the original diagnosis, and reporting this as a case of epidemic or Asiatic cholera. During the month following this, nine other cases occurred in New York City, and one in New Brunswick, N. J., in which a diagnosis of Asiatic cholera was made, either on the ground of the biological examination, or, in two or three cases where no biological examinations were made, on the clinical history and the association of the patients with cases of Asiatic cholera. Twenty-four suspicious cases in all were examined biologically, in a number of instances repeated examinations being made.

Of the eleven cases of true epidemic cholera (including the New Brunswick case) nine died; among the others, which biological examination showed to be sporadic cholera, no deaths occurred. The clinical history in all the cases of true cholera was nearly the same, namely: vomiting, watery diarrhœa attended with severe cramps in the abdomen and legs, collapse, and in most cases death; the whole duration of the illness varying from six or eight hours to thirty-six hours, and in one instance to five days.

The material used for the biological examinations in most of the cases, which proved to be epidemic cholera, was obtained from the intestinal contents after death, as these cases, with one exception, occurred before or almost immediately after they were first seen by the Health Department Inspectors. In one case the intestinal discharges passed before death were examined, and in the suspicious cases (which proved to be sporadic cholera) the intestinal contents were always the material submitted for examination. In one or two instances the material presented for examination was in the form of soiled clothing. The results of the biological examinations in all the cases of epidemic cholera were identical, the same microörganism (the cholera spirillum) showing the same biological characteristics in all respects, was found. In some of the cases the cholera spirillum formed more than 90 per cent of all the microorganisms present in the intestinal contents.

The anatomical lesions and postmortem appearances in all of the cases were the same, and are so striking and so unusual in autopsies in this latitude, as to constitute in themselves strong but insufficient ground for a diagnosis.

The cultures from several of the latter cases before an official report was forwarded to the Health Department, were examined at my request by Dr. T. Mitchell Prudden, and Dr. Henry P. Loomis, and the diagnosis was confirmed by them, and their names were appended to the reports. After several cases had occurred, that there might be ample confirmation of the original diagnosis, cultures were sent to Dr. Harold Ernst, Professor of Bacteriology in the Harvard Medical School; to Dr. George M. Sternberg, Deputy Surgeon General of the United States Army (who, during the epidemic, at the suggestion of the Advisory Committee of the Chamber of Commerce, and at the request of Dr.

Jenkins, was detailed as Consulting Bacteriologist to the New York Quarantine Station); Dr. J. M. Byron, Director of the Bacteriological Division of the Loomis Laboratory (who, during the epidemic, was placed by Dr. Jenkins in charge of the hospital at Swinburne Island); Dr. Wm. M. Welch, Professor of Pathology in the Johns Hopkins University, Baltimore; and to Dr. Petri, Chief of the Bacteriological Department of the Imperial Board of Health, Germany. The identity of the organisms found in these cases with that of the cholera spirillum of Koch, was confirmed by all of these observers, and, furthermore, Drs. Byron and Sternberg confirmed the identity of these organisms with those found in the cases that occurred on the cholera infected vessels and on Swinburne Island. Unusual precautions were taken in this matter, that there might be no possibility of doubt as to the nature of the disease with which we had to deal.

The postmortem appearances and the anatomical lesions in the cases of Asiatic cholera, eight in number, in which autopsies were performed, were very striking and were practically indentical. The face had a peculiar drawn expression, the cheeks and eyes were much sunken, and the cheek bones were very prominent. The extremities of the nose, fingers and toes were shriveled and often cyanosed. The extremities (arms and legs) were semi-flexed, with the toes drawn under and the fingers clenched, rigor mortis was very much marked, and in some cases the temperature postmortem remained high for some hours. On opening the abdomen, the coils of intestines presented a peculiar rosy tint, which was especially marked in the coils of the ileum. The small intestines especially were, as a rule, markedly distended with fluid contents. All of the parenchymatous organs showed cloudy swelling and appeared congested. The brain and its membranes were also congested. The blood everywhere was fluid, or showed only a few soft, dark clots.

BACTERIOLOGICAL EXAMINATIONS IN SUSPECTED CHOLERA CASES, SEPTEMBER AND OCTOBER, 1892.

Number.	Sample Received.	Character of Sample.	Direct Microscopical Examination.	Culture Results.	Rel. Prop. of Cholera Bacilla to Total No. of Bacteria.	Results Reported.	Remarks.

31	Oct. 7 .	Stomach contents . .	"	" " .	. . . .	Oct. 9 .	

The mucus membranes of the stomach and intestines presented few changes to the naked eye, excepting marked prominence and swelling of the patches of Peyer and the solitary follicles in the lower part of the ileum. The intestinal contents showed in all cases a striking absence of biliary coloring matter, or anything resembling ordinary fæces. The intestinal contents were usually large in amount, had a gruel-like consistency, and a slightly pinkish hue. If placed in a vessel and allowed to stand some hours, a white sediment formed, leaving an almost clear supernatent fluid having a pink tinge. The sediment was found on microscopical examination to be made up largely of desquamated epithelial cells from the mucus membrane, mucus, micro-örganisms, and granular detritus.

The bladder was usually empty. In a few cases there was a marked peculiar dryness of all the organs.

The postmortem appearances and the anatomical lesions, together with the absence of any sufficient anatomical cause for death, produce a picture that is unlike that seen in any other disease, excepting those comparatively rare cases of sporadic cholera, which present the same clinical histories.

In my annual report to this department, I shall give a description of the method employed in the biological diagnosis of Asiatic cholera.

A table is appended giving the important data regarding the specimens which were examined bacteriologically.

Copies of the letters received from the different bacteriologists who have examined the cultures, are also appended. Respectfully submitted,

(Signed) HERMAN M. BIGGS,
Chief Inspector,
Division of Pathology, Bacteriology and Disinfection.

CLEVELAND, O., Dec. 1, 1892.

HON. TOM. L. JOHNSON AND HON. V. A. TAYLOR, MEMBERS OF CONGRESS FROM THE 20TH AND 21ST DISTRICTS OF OHIO.

Gentlemen:—The dangers to be apprehended the coming year from cholera, and every year from yellow and typhus fevers, and other fatal diseases which may be imported from abroad, are such as to cause all good citizens anxious concern. The magnitude of the work of guarding our National frontiers against the importation of infectious and contagious diseases, the efficiency of quarantine if thoroughly and properly applied, the fact that the people in the interior are no less interested than those upon the borders of the country, and the further fact that the States acting separately are unable to properly establish and enforce efficient quarantine; all these considerations point to the conclusion that the general *government* should assume control of coast and border quarantine. The present organization and equipment of the Marine Hospital service and the excellent work heretofore done by that service are evidence, in our opinion, that the Marine Hospital Corps is amply able to enforce quarantine if its powers are sufficiently enlarged and adequate funds are placed at its command. Neither the present powers of the Marine hospital service, as we understand them, nor such appropriations as have heretofore been made are at all adequate to meet the present emergency. We, therefore, your constituents and members of the Cuyahoga County Medical Society most earnestly request you to use your utmost endeavors to secure action by Congress early in the present session upon the matters herein set forth. To accomplish the desired ends of such legislation early action by Congress is a necessity in order that time may be given to prepare for the work. In thus urging National Quarantine we do not fail to recognize the efficient work of the Health authorities of New York City during the present year. Indeed the success of local quarantine at the Port of New York and other sea-ports but emphasizes the need of National quarantine to the end that all points upon our borders may be guarded with equal efficiency, and, as this is a matter which concerns the whole country, it is but just that the whole country should bear the burden of expense. We would also urge upon your attention at this time the obvious fact that preventive medicine is so related to internal conditions and to foreign immigration—in short, to the "general welfare" and is of such importance, magnitude and dignity that the general government should no longer neglect to give it proper recognition. Either the powers of the Marine Hospital Service should be so enlarged as to meet the requirements, or a Department of Public Health should be established and ample means provided to enable such department to perform its legitimate duties.

We earnestly hope that the views above set forth may coincide with your own and that you may earn the lasting gratitude of your constitutents and of the whole country by pushing forward the cause of public health.

Rspectfully submitted,

W. J. SCOTT, M.D.
W. A. KNOWLTON, M.D., } *Committee.*
L. B. TUCKERMAN, M.D.

ISAAC V. HIMES, M.D., *President.*
JULIUS WOLFENSTEIN, M.D., *Secretary.*

MISCELLANY.

DR. RICHARD H. DAY died at Baton Rouge, La., December 4, 1892. He was born at Bladensburg, Md., June 9. 1813.

AT the annual "business meeting" of the Washington Obstetrical and Gynecological Society, held Oct. 21, 1892, the following officers were elected for the ensuing year: President, Dr. D. W. Prentice; vice-presidents, Dr. H. L. E. Johnson, Dr. H. D. Fry; recording secretary, Dr. G. Wylie Cook; treasurer, Dr. Geo. Byrd Harrison; corresponding secretary, Dr. W. Sinclair Bowen.

OFFICIAL LIST OF CHANGES in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from December 10, 1892, to December 16, 1892.

Lieut.-Col. William D. Wolverton, Deputy Surgeon-General U. S. A. is relieved from duty at Ft. Schuyler, N. Y., and will report in person to the commanding officer, Watervliet Arsenal, West Troy, N. Y., for duty at that arsenal.

First Lieut. Charles Willcox, upon the recommendation of the Medical Dept. of California, will report to the commanding officer, Presidio of San Francisco, for temporary duty at that post, until the departure from Angel Island, Cal., of Major William H. Gardner, Surgeon, when he will proceed to Angel Island, and report to the commanding officer of that post for temporary duty.

Capt Adrian S. Polhemus, Asst Surgeon U. S. A., is hereby granted leave of absence for two weeks on surgeon's certificate of disability, with permission to apply for an extension of two weeks.

OFFICIAL LIST OF CHANGES in the Medical Corps of the U. S. Navy, for the Week Ending December 17, 1892.

P. A. Surgeon E. R. Stitt, from receiving ship "Franklin" and to hospital, Norfolk, Va.

P. A. Surgeon J. F. Keeny, from Naval Hospital, New York, and to the U. S. S. "Ranger."

P. A. Surgeon T. A. Berryhill, from U. S. S. "Ranger" and to the Fish Com. Str. "Albatross."

P. A. Surgeon F. W. F. Wieber, from the Fish Com. Str. "Albatross" and granted one month's leave.

Asst. Surgeon G. T. Smith, from Coast Survey Str. "Hassler," proceed home and wait orders.

Asst. Surgeon F. G. Brathwaite, from the U. S. S. "Fern" and to the U. S. S. "Chicago."

Asst. Surgeon J. S. Hope, from the receiving ship "Franklin" and to the U. S. S. "Fern."

Asst. Surgeon J. M. Whitfield, from the U. S. S. "Chicago" and granted one month's leave.

OFFICIAL LIST OF CHANGES of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the eight weeks ended December 10, 1892.

Surgeon George Purviance, detailed as chairman of Board to consider changes in uniform. December 6, 1892.

Surgeon W. H. H. Hutton, relieved from duty at Cape Charles Quarantine, to rejoin station. November 29, 1892.

Surgeon John B. Hamilton, granted leave of absence for six days. November 18, 1892.

Surgeon H. W. Sawtelle, granted leave of absence for seven days. November 9, 1892.

Surgeon H. W. Austin, detailed as member of Board to consider changes in uniform. December 6, 1892.

Surgeon G. W. Stoner, granted leave of absence for fourteen days. December 9, 1892.

Surgeon John Godfrey, to proceed to the City of Mexico on special duty. November 22, 1892.

Surgeon Fairfax Irwin, to proceed to Europe on special duty. November 22, 1892.

Surgeon F. W. Mead, detailed as recorder of Board to consider changes in uniform. December 6, 1892.

Surgeon H. R. Carter, relieved from duty at Cape Charles Quarantine, to rejoin station, October 20, 1892. Relieved from duty at Cincinnati, O.; assigned to duty at Norfolk, Va. October 26, 1892.

P. A. Surgeon C. E. Banks, granted leave of absence for fifteen days. October 24, 1892.

P. A. Surgeon A. H. Glennan, granted leave of absence for thirty days. October 26, 1892.

P. A. Surgeon W. D. Bratton, granted leave of absence for thirty days. November 10, 1892.

P. A. Surgeon J. O. Cobb, granted leave of absence for sixteen days. December 7, 1892.

P. A. Surgeon G. M. Guiteras, relieved from duty at Gulf Qurantine, assigned to temporary duty at Balitmore. Md. December 1, 1892.

P. A. Surgeon H. D. Geddings, to report in Washington, D. C., for special temporary duty. November 30, 1892.

Asst. Surgeon S. H. Hussey, to proceed to South Atlantic Quarantine for temporary duty. October 26, 1892.

Asst. Surgeon J. C. Perry, when relieved at Norfolk, Va., to rejoin station at Mobile, Ala. October 26, 1892.

Asst. Surgeon G. B. Young, granted leave of absence for twenty-one days. October 27, 1892.

Asst. Surgeon W. G. Stimpson, to proceed to Baltimore, Md., for temporary duty. December 5, 1892.

Asst. Surgeon C. H. Gardner, ordered to Portland, Or., for temporary duty. October 25, 1892.

Asst. Surgeon J. A. Nydegger, to proceed to Gulf Quarantine for temporary duty. December 1, 1892.

Asst. Surgeon Edgar Strayer, detailed as inspector of immigrants, port of Boston, Mass. November 22, 1892.

The Journal of the American Medical Association

Vol. XIX. CHICAGO, DECEMBER 31, 1892. No. 27.

ORIGINAL ARTICLES.

THE UNITED STATES NAVAL RATION.

Read in the Section of Physiology and Dietetics, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY SURGEON C. A. SIEGFRIED, U. S. N.

In accordance with the desire of the American Medical Association, made known to Surgeon-General J. Mills Browne of the Navy, by the officers of the Section on Physiology and Dietetics, I have the onor to submit the following contribution on the S. Naval Ration and the system of dietetics comonly in use in the Naval Service.

You desire to know how we nourish and subsist he American Naval man, upon what principles and scale his dietary is composed, the nutritive and dynamic values of the articles composing it, and the general results both to himself and his country. As the problem implies some retrospection, and as the principles and knowledge guiding us are universal, I beg to be allowed to give some account of the present *systematic training of vast bodies of men for armies and navies, and the bearing this has on the* hygiene and development of whole nations and millions of human beings.

The *progress of the arts and sciences* in recent times has had its due influence in the evolution of the present complex military and naval rival organizations of civilized nations. These armed bodies [illegible] the Continent of Europe, where the play of political and economic problems and forces is greatest, unhappily absorb the bulk of the genius and talent of mankind, and the training and disciplining for effective use at the least cost of these hosts of men has become the chief end and aim of national ambitions. It has called into existence, aside from the material constructions and equipments of destructive offense and defense, a vast amount of practical skill and the highest arts of scientific hygiene, in producing and conserving the physical adaptability and stamina of men by the use of proper clothing, housing, food and water supplies, periods of work and rest, and the cultivation of their capacities physical and mental. In these services our profession is mostly concerned with disease prevention and waste of life, and under very favorable circumstances, for evil results quickly make themselves felt, and we have to deal here with the causes of more losses than the casualties of the most sanguinary wars in history. A bad dietary and tainted water quickly render a force of men useless, whilst comparatively few are killed in battle. There has thus been produced a very costly, highly efficient and intensely destructive agency, and no department of science and experience is left unransacked to promote these ends.

But as all these things are but inanimate contrivances and inventions needing *for their essential uses the touch of man, it is our* part to produce and preserve to the extent of all his powers the more highly endowed and delicate human machine, so that he *may not fail* in his part in the hour of trial, that waste of life and loss of treasure may not be the final result.

Vast national forces, in countries where every able-bodied man must serve his allotted time with the army or navy according to his place in society, are in reality vast schools, and by many publicists and hygienists are looked upon as blessings in this sense. The ignorant peasant and lowly laborer are taken from often barbarous surroundings, cleansed, vaccinated, and set upon a humane basis of existence more favorable in every respect for *their improvement.* They are removed for a time from the deadening labor of the fields and factory, the mind is opened, they are trained not only to *arms but in the* elements—if no more—of a *common* education—by their associations and daily tasks. His body is cultivated in all parts, including his mind, for obviously this human machine is made more efficient and expert as a war factor in proportion as his mental and physical development has advanced.

It is said with justice that since universal military or naval service has come into effect in European countries, many problems relating to sectional antipathies, as well as the causes of disease and spread thereof influencing whole provinces, are being removed. This is notably so in Italy, and is a powerful factor in the regeneration and unification of that country. So from the standpoint of hygiene, and as medical men, it cannot be an evil that these hosts of human beings are so collected together, groomed, trained and fed as science dictates; for once implanted in them by the power of the State, these habits and impressions must to a great extent remain with them on their return to their former pursuits and civil occupations; and in so much do they and the community to which they belong benefit. It is not too much to say that this universal service is in Europe a great uplifting agency, and on the other hand wars are happily not more frequent than *under* previous conditions.

In those early periods in history when *men fought* their battles in rude boats propelled by manual labor, a rude commissary effort was carried on by the warriors' servants and differing not essentially *from his* daily fare ashore, whilst the absences from bases *of* supply were short.

In the course of time as the art of navigation and the knowledge of astronomy and geography grew, explorers traversed all seas, and in making long voyages food supplies became progressively less fresh and full, and consisted mainly of the coarser cerealia, dried and salted meats, spirits, and some live *stock.* Coincident with these long absences from land and fresh food grew the list of deaths, directly and indirectly from these deprivations, and chiefly from the lack of those little appreciated food elements in a fresh state derived from succulent plants and animal flesh. So that accounts of early voyages are often but doleful narratives of gradually increasing suffering and death dependent upon these deprivations and length of time at sea. The losses from scurvy in the best appointed navies up to 1840, comprise the bulk of the mortality tables; and in the commercial marine the disease still occurs, due usually to the rapacity of owners in fitting out ships with insufficient and adulterated food supplies. Scurvy among seamen, and even on land, up to the end of the last century, has been a classic theme in the study of causes and the sequelæ of improper and insufficient dieting, and the present appreciation of the disease may not inappropriately be referred to here. It has absorbed the attention of naval medical men because of the magnitude of the losses in life, exceeding in the past that from all other causes combined.

It was not uncommon for a naval vessel in three years of remote foreign service to lose a sixth or even more of her crew, and in the voyages of discovery a century and a half ago, often but a handful returned of the hundreds who originally ventured, and these misshapen, brutalized specimens of humanity. To the immortal credit of Captain Cook, he was the first to furnish the experimental proof on a large scale of the value of succulent fruits and vegetables and their acid juices in preventing and curing scurvy. This occurred in 1772–75, during his second voyage, when with a crew of 118 men he circumnavigated the globe, and brought all but four home with him—three dying from accident and one from consumption. This memorable event, and successful dieting, for which he received the medal of the Royal Society, took place only thirty years after Anson's voyage of discovery, in which out of 900 men he lost 600 from scurvy in three years. Yet like all reforms in hygiene, the lessons of Cook's experience and the pleadings of naval surgeons had but little effect, and scurvy figured heavily in naval mortality tables up to fifty years ago. Cook's vessels in 1772 were supplied with malt, sour krout, salted cabbage, "portable broths" and soups, mustard, marmalade of carrots, inspissated juice of wort and beer, and as much as possible of live stock. He knew the value of fresh berries, he cooked grasses and greens with the dry legumes and cereals, he used the fresh flesh of all animals and birds, and he even distilled sea water in times of scarcity. To produce dryness and to fumigate between his narrow decks he used the fire and smoke from portable iron baskets. By these various means he successfully traversed (in his ship the "Resolution," of less than 400 tons burden) the seas from the latitude of England to south latitude 71°, in the tropics, and antarctic ice regions, alternately, and encircled the globe.

Scurvy pathologically is characterized by the effusion of semi-organizable fibrinous material in the tissues of the gums, between the straie of muscles, and periosteum and bone, by ecchymoses, and blanched tissues. In the blood the red cells are diminished, its albumen and fibrin are relatively increased, and there is no great decrease in the amounts of potash and other salts. Some have held that potash salts are deficient in scorbutic diets and in the urine of those ill with the disease, but this is counterbalanced by the fact of success following not potash loaded aliment, but the prompt curative effect of substances holding naturally in solution and in the fresh state the organic salts of fruits and succulent vegetables, as the citrates, lactates, tartrates, etc., best exemplified in lime juice, potatoes, acid vegetables and fruits. Ralfe concluded that the primary alterations in scurvy depended on an alteration between the various acids, organic and inorganic, and the bases found in the blood, by which, *a*, the neutral salts, as the chlorides, are either increased relatively at the expense of alkaline salts; or, *b*, that these alkaline salts are absolutely decreased. Thus is produced a "normal" alkalinity of the blood, and he suggests that this diminution produces the same results in scurvy patients as happens in animals when their blood is reduced in alkalinity by injecting acids or feeding acid salts; namely: dissolution of blood corpuscles, ecchymoses and blood stains on mucous surfaces, and fatty degenerations of muscle and secreting gland cells. The disease is a maximum expression of malnutrition dependent on chemical alterations of the blood and fluids of the body, and on specific changes in the normal metabolism of protoplasm, and its study bears a direct and suggestive relation to our subject—the proper nutrition of the body by well proportioned diet.

Though full generous food stuffs in moderately fresh state do prevent scurvy, yet it occurs when from unforeseen circumstances the diet fails in some of these requirements, and it is customary to provide mariners with antiscorbutics properly so-called. The value of lime juice was known from 1573 (Solomon Albertus), 1593 (Sir Richard Hawkins); and in 1795, through the importunity of Blane, it was regularly issued to the English navy. It is not in the regular U. S. Naval ration. In the English Arctic experience in 1873–75, it was found that scurvy occurred when lime juice was omitted, even though pemmican and preserved potatoes were used. From Kane's time raw meat is of known value. It is to the absence of the substances of the fourth group of aliments that scurvy is due, and these include those salts and bodies in tissue solutions to which much of the catalytic and dialytic properties of organic fluids, and exchanges in normal nutrition or metabolism are due. To this group, and with variety of food elements as a whole, are probably also due the more thorough elaboration of the digestive ferments and enzymes. There does not seem to be in scurvy diets any deficiency of sodium, iron, lime, magnesia, or the salts of potash or phosphoric acid, when it is considered how much phosphoric acid there is contained in the cerealia and meats, and yet the disease occurs. The same can be said of sulphur in relation to meats and the leguminosæ.

There remains then only the inorganic elements, the salts and the combinations of alkalies with those which form carbonates in the system, viz.: lactic, citric, tartaric and malic acids. The salts containing them are at first neutral, afterwards alkaline, from their conversion into carbonates; they then play a double part, and moreover, when free and in the presence of albumen and sodium chloride, these acids have the peculiar power of precipitating albumen, or perhaps of setting free hydrochloric acid. Without these carbonates there is likely to be an excess of acids in the system, from the production of phosphoric, sulphuric, uric and hippuric acids in ordinary functional activity, and the only alkali in the body is the formation of ammonia; hence the importance of these antacids. Yet the administration of carbonates of the alkalies does not cure scurvy, but it is the particular action of these organic acids which in practice prevents and cures it.

Happily this scourge has disappeared from mortality lists in navies, yet from this grade of extreme malnutrition to the less appreciated faulty body conditions and manifest ill-health, occurring both ashore and afloat, is not many steps, whether among the poorer laborers of the fields and factory, or in luxurious homes. The tea and bread diet of the factory hand, the ham and hominy of the farmer, the confection-crammed child of wealth, and the heavily loaded club man—whose tissue cells by overstimulation go from cloudy swelling to fatty degeneration —all these exemplify grades of malnutrition and consequent disease in various forms. The lack of correct nutrition is keenly felt in family lines, in "diatheses," and in body states comprised in classes of disease wherein there is vulnerability of certain tissues, and irregular functioning leading to early dissolution. Whether we use the terms meaning observed facts such as phagocytosis, chemotaxis, and the anti-toxic properties of normal tissue cells and blood serum, these disease-resisting properties are inherent to functionally active well balanced organizations under conditions of correct nutrition in the larger sense. The well known nurtureless milk from the breast of a poorly fed woman is not alone deficient in nutrients but contains at times (recent observers in *Virchow's Archives*), the microörganisms of suppuration.

The cravings for quantity of the glutton, the strange perversions in kind and quality, the excesses of the orgie-loving seaman, are of deeper significance than is ordinarily accorded them. By long custom and necessity existence can be endured on marvellously altered food, both in quantity and quality, yet there grows with such conditions abnormal sense and intellection faculties, persistence follows from uncontrollable and ineradicable habit; and finally, there is perpetuated a blighted, low human type, prone to crazed excesses, criminalities and abbreviated existence. Such populations are to be seen in all countries, in the mining and factory regions of the foremost nations as well as among the older oriental nations and barbarous peoples. Laws based upon philanthropy and knowledge of food requirements are of slow growth, due to the difficulty of dealing with the selfish interests and unconscious ignorance of the vast majority of mankind. Peas may not be greened with copper sulphate for use in France, but may be so treated for use in other countries, the latter clause being added by the power of selfish interest. Finally we are justified in saying that disease may be produced by alterations in quantity, excess or deficiency; by imperfect conditions of digestibility, state of integrity, preparation and cooking; and by special characters of quality.

The steps leading to the present recognized principles of healthful dieting reach back to the time of Aristotle, who said that the organism requires food supplies for three purposes—growth, heat production, and to make up for loss by bodily excreta. He thought that the formation of heat took place in the heart by a process of concoction, the heat so formed being distributed to all parts of the body by means of the blood, while the respiration was regarded as a cooling process. Galen compared the metabolic processes to the phenomena going on in a lamp; the blood represents the oil, the heart a wick, and the lungs a fanning apparatus. Van Helmont and the intro-chemical school argued that the metabolic processes are fermentations, whereby the food is mixed with the juices of the body. Since the middle of the seventeenth century—the time of Boyle—the knowledge of metabolism has followed the development of chemistry.

A. V. Haller regarded heat as due to chemical processes—the food continually supplying the waste which is excreted from the body. After the discovery of oxygen, Lavoisier formulated the theory of combustion in the lungs, whereby CO_2 and water were formed. Mitscherlich compared the decomposition processes in the living body with putrefactive processes. Magendie was the first to emphasize the difference between nitrogenous and non-nitrogenous foods, and he showed that the latter alone were not able to support life.

The greatest advance was made by the illustrious Liebig, who in fact laid the foundation of our present knowledge, though his division of foods into the plastic and respiratory or oxidizing foods is no longer tenable. The labors of the French Gelatine Commission have also been of use in the studies of nitrogenous foods. The more recent and accurate knowledge of the chemico-physiological processes of normal metabolism has been chiefly gained by the labors of the Munich school of investigators, Pettenkofer, Voit and others. Proteid tissues are not alone the result of proteid food, and the accumulation of fat in the body is not altogether due to excessive consumption of fats and carbohydrates. Contrary to the former general belief it is now known that the nitrogenous tissues are not used up during hard labor any faster than when at rest, and that increased muscular exertion is attended by increased consumption of stored up fat. We may liken the human body to a machine composed mainly of proteid tissues, keeping its integrity by supplies of nitrogenous foods and its working capacities by non-nitrogenous foods; and of these latter fat is of peculiar conserving and economic importance. Further progress in the metabolism of protoplasm, as also the causes of the phenomena in disease processes resulting from changes in chemical constitution of tissues, must in great part come from the workers in the field of chemistry. It is realized that the whole class of unstable proteids, emulsions, and nutritional solutions from food digestions, are difficult to elucidate at their distinctive values, and here the grasp is frequently at shadows in the search for substance. May not this apparently insurmountable barrier exist in virtue of the vital principle—the unceasing molecular change in living tissues?

In a public service like the Navy, with careers spent away from the centres of learning and research, and with barely sufficient room on shipboard for the common necessities of the animal man, it is not expected of us that we carry the torch. We endeavor to apply the scientific truths gained by our more fortunate brethren on shore. Since the beginning of the present century but little original work in dietetics has been done by naval men, and the writings of Lind, Blane, Trotter, and Fletcher are still the classics in the English language, and we all profit by the works of the lamented Parkes. Recent writers have however done much good wook in several directions, notably the French and Germans, but dietetics has not been given the same prominence as other conditions influencing health on shipboard. Scientific dietetics has conduced to greater economies in the French, German, and Italian navies, and they have graded the food allowances to the amount of work required. It is recognized that if men are to work or fight well they must be fed well. In our navy the subject might be further developed, not in any great additions to quantity or variety, but in the now recognized possible economic adaptations—the hardest worked to be the best fed, and changes in character in accordance with the nature of the work or service, the climate and season. From time to time changes in sea dietaries have taken place in keeping with the general increase of knowledge regarding food stuffs, and it can be said now that naval seamen as a rule actually get adequate food and the full value of their lawful allowances.

From the beginning of our national existence the laws state "All contracts and purchases of supplies for the military and naval services shall be made by or under the direction of the chief officers of the war and navy departments respectively" (July 1798). The naval subsistence was in the hands of the "pursers," now the paymasters under the direction of the Bureau of Provisions and Clothing in the Navy Department at Washington. The contract system and the lowest bidder consistent with good quality, is in vogue, surrounded by many safeguards. Supplies are advertised for with particular and full specifications in every detail of quantity, quality, packing, preservation and methods of keep, and distribution in convenient packages and portions. Stores are used within as short a time of their packing as possible, and much ingenuity is exercised in stowage, size and shape of casks and cases, and in issue.

Naval dietaries up to 1798 were truly deplorable, and that life was endured at all in working health is a marvel. But then navies, up to our times, were services of adventure, discovery, fighting and spoils, and thus attracted men; and if necessary men were impressed or forced into navies and ships. The famous mutiny at the Nore in 1797, in which several thousand British sailors took part, was due to wretched rationing, and one of their complaints was that the sailors' pound was only 14 ounces, because of the eighths subtracted from their allowances by their officers by law and custom, in fact this was the chief source of pursers salaries in those days. The daily ration then was composed of albuminous principles 4.58, fats, 3.14; carbohydrates, 12.83, and salts 1.20 ounces.

Pursers also sold stores and food stuffs, and the crews added to their diets by purchase. In those days such dietaries were common in navies, and yet great wars at sea were carried on, and courage and strength were an English sailor's characteristics. Prizes and plunder were no doubt inspiring agencies in the old sea life, and made up for lack of pay and food allowances; and armed ships did much as they pleased with other people's property, considering the constant wars, discovery voyages, and legalized piracies(?). Not infrequently noted commanders were freebooters in one hemisphere and court noblemen in the other. With the emergence of the world from the wars of the last century, navies became more and more peaceful patrols of the sea, and the chief food supplies became and now are the legal allowances—the ration. From that time on "salutary changes" were frequently made and with these came ameliorations and improvements in mortality tables; typhus fever, ulcer, dysentery and scurvy disappeared and diminished, and the sailor was no longer classed with the lowest of human beings.

In our own navy the ration has been over-hauled and changed in some direction at periods of about twenty years. When spirits was abolished in 1862, its cost (the ration) was raised from 25 to 30 cents, and it is so now when commuted. The ration, substantially as now, was in 1842 established by Congress. "The ration, shall consist of 1 pound of salt pork, with ½ pint peas or beans; or 1 pound salt beef, with ½ pound flour, and ¼ pound raisins, dried apples, or other dried fruits; or 1 pound salt beef, with ½ pound rice, 2 ounces butter, and 2 ounces cheese, together with 14 ounces biscuit, ¼ ounce tea, or 1 ounce coffee, and one gill spirits; weekly ½ pint each, pickles, vinegar and molasses."[4] As substitutes, "fresh meat 1¼ pound, for salt beef or pork; 1 pound vegetables or sour krout for the articles issued with the salt meats. 1 pound fresh bread, 1 pound flour, or ½ pound rice for 14 ounces biscuit; ½ pint wine for a gill of spirits. Spirits not allowed persons under 21 years of age; others may relinquish and receive commutation therefore." This scale was only inferior to the present one in actual values by reason of imperfect packing and preserving methods in use in those days, combined with long sea voyages. It is difficult to correctly estimate nutritive values of allowances and descriptions of the articles used at that time, and frequently years would elapse from the putting up of an article to its consumption. Hence enormous fluctuations in values.

In 1861, the law provided preserved meats and dessicated vegetables, for the first time, and the spirit allowance was abolished shortly afterwards. More latitude was given for substitution and variety. The canned and dessicated food stuffs met with little favor from the men and the suppression of Jack's grog was considered nothing short of a crime, and caused much discontent at the time. The total lack of spirit, beer, or wine, in a sea dietary is not in accord with the opinion of many hygienists and seagoing people, and the law has not improved the content with the many inexorable deprivations of sea life. This ration was satisfactorily used during the civil war. In 1872 an additional ounce of coffee and sugar was allowed for an early breakfast. Sailors so long as they have money, constantly and freely add to their daily fare from market or "bumboats," which come alongside at meal times in all parts of the world. Fruits, bread, and eggs in great quantity, are consumed in this way; and great bagnets filled with potatoes are carried to sea, in addition to their allowance. It has occurred to me that salt meats rarely in practice come up to their theoretical values, and this, with some deficiency in fats, usually due to waste in cooking, has caused the sometimes prodigious-egg consumption from bumboats. All seamen desire large rations and naturally prefer fresh food. They are also great growlers and look with suspicion upon innovations in their rations, and the best intentions are in this regard often thwarted by them.

In 1884, the Hon. Secretary of the Navy appointed a board of officers to revise and advise concerning the ration, and the present regulations date from that time. The list of articles was amplified and in many respects the food, meal hours, and methods of preservation, packing and issue, were improved, so that on the whole, while not substantially increased in quantity over that provided by law of 1861, the ration is superior to that of other naval services, and compares well with standard and model dietaries. But the nutritive and dynamic values are, according to my calculations, inferior to that of some classes of laboring men and mechanics in this country; and, it is lacking in a just proportion of elements, the fats being deficient in the common sea issues and the albuminates in the fresh issues.

Among the questions put to the '84 Board were the following: Is the ration sufficient in quantity and variety, and is it necessary to exceed present cost? Others related to preparation of supplies, commutations, and cooking. They reported that the ration was deficient in fat and nitrogenous principles, and they made appropriate recommendations. One of the most important recommendations made, the training of a class of competent cooks, was not acted upon. With us as with you ashore, the amount of waste, the difference between the amount of food material supplied and the amount consumed, is enormous, certainly as much as 25 per cent., and much of this would be prevented by better cooking. Potatoes are roughly cut to pieces not pealed, the fat of meats is boiled or burned off and becomes "slush" (common ships grease for lubrication purposes), flour is made into poor breads and indigestible "duffs," and methods of haste and ignorance, combined sometimes with sharp practices, prevail in some instances with the cooks and mess attendants. It is interesting to note that as a rule the officers—in answer to inquiries from the '84 Board—had nothing but praise for the ration in amount and nutritive value, their criticisms relating mainly to matters of detail in care, preparation and issue. On the other hand six seamen emphatically said "no, they never had enough to eat when on their legal rations," "it was not varied enough; that the salt beef was always bad; they desired better cooking facilities; and to commute 25 per cent. of ration, and with the money buy other food."

As an instance of what can be done in managing allowances of food to their best uses, Col Burnett, of the First Royal Rifles, of the English army, found his men suffering (in 1889) from lack of food, due to wretched distribution and cooking. By careful management and with no change in cost, he brought the carbon up from 4,588 grains to 4,912 grains, and the nitrogen from 276 grains to 344 grains per diem, the men being satisfied instead of suffering semi-starvation, and receiving in ounces: albuminates 4.92, fats, 2.96, and carbohydrates 16.36. It is asserted that with proper care the English army and navy allowances are amply full, and exceed the continental services in nitrogenous matter. In general the U. S. Navy ration is somewhat superior to the English naval ration in albuminates, and much superior in the same element to all European navies. Bread is the staple in continental rations, 1½ pounds being the common daily allowance, whilst ours is but 1 pound. But we excel them in meats, butter, sugar, and beverages, the more satisfying elements. Condiments are not supplied in our ration, contrary to other services, the men buying it, and they obtain salt from pork barrels.

For particularly arduous duties, or exigencies of polar service, additional and appropriate food is supplied by the government and according to the character of the service. It is now impossible to carry in modern warships great amounts and varieties of food stuffs; the conditions have changed since steam alone has become the motive power, and ships keep the sea no longer than the supply of fuel lasts rarely over a fortnight. It is also difficult to make in set terms of law a single rigid dietary for so many varying circumstances of duty, climate, and labor, so that latitude and simplicity of application are essential, the nutritive standard being kept in view. If subsistence alone were the object aimed at the rations could be graded according to the work done by individuals, and the crew of a ship could be divided into three classes, first the moderate workers, second, the hard workers, and third, the severe hard workers. But it is better and simpler in practice to have one scale on shipboard, the class of severe laborers—the firemen—could be allowed an additional third or half ration. Most foreign navies have adopted the sliding scale here indicated. The muscular exertion of the men on a modern war ship varies from writing accounts and stores keepers; watching, moving about in a certain space for hours at a time; actively attending moving machinery; drilling with small arms and great guns, to the hardest labor known—that of stoking marine engine furnaces in a closed fireroom at a temperature of from 110' to 175' F. The working life of a modern steamship firemen is given at about nine years; exhausted hearts, and chest diseases due to sudden excessive and abnormal conditions of heat and cold, combined with the strain of great labor in a confined space kill these men up prematurely. Such men require much nutrition, and in most great navies are the higher paid and fullest rationed class. The average seaman or deckman requires a less full diet, and finally about 10 per cent. need only the moderate work scale. So that an average modern warships company is composed of:

	Nutrients in Grams.			Potential Energy in Calorics.
	Protein.	Fats.	Carbohydrates.	
25 per cent. of men in severe labor, requiring	225	200	650	5407
65 per cent. of men in hard work, requiring	175	150	550	4367
10 per cent. of men in moderate work, requiring	125	125	500	3735
(Estimated model), an average of . . .	175	158	566	4507*
Present ration	157	75	549	3615

*In foot tons, 6895.

Naval apprentices for the first six months, usually spent in harbor, are subsisted at the commuted cost of the ration, 30 cts, and this supplies an ample and varied dietary. Amounts are not restricted and the fare is quite the equal of the ordinary American home table. These boys, from 14 to 18 years of age, begin the day with cocoa and milk, breakfast (with meat four days in the week) at 8. dinner at 12 (with meat) and supper at 6, the usual navy meal hours. On occasions men or boys are put on "bread and water," in confinement, with full ration every fifth day. The officers and naval cadets subsist themselves the ration being commuted. On long sea voyages they often use the regular ration and the writer (in a ships company of 300) once subsisted fairly well and without hardship for five weeks on three fourths of the ration, though the men were restless and murmured. By law, commanding officers of ships, from accident or unforeseen scarcity at sea, can curtail the food and supplies of any description. For very obvious reasons naval dietaries should be constructed upon generous principles, for an efficient naval vessel must be manned by actively strong, and intelligent men and officers; hence a model diet must lean to proteids and fresh supplies, consistent with keep and transport.

[1] 20 per cent. waste. Calculated from total fore and hind quarters.
[2] 18 per cent. waste. Potatoes, onions, cabbage, etc., mixed.

In the French navy the cost and kind of the ration varies from 11 cents to 27 cents according to the position of the man. Commutation is not common in any European navy, the men being fed closely and paid on a similar plane, whilst their dietaries partake of the national characteristics. Maccaroni figures in the Italian, sour krout in the German (and it is unsurpassed as a sea vegetable), brandy in the French, and oil, wine, cheese and beer, in most of their lists. Meats are rather limited, and bread and biscuit large—to 1½ pounds in most of them. The Chilians allowed their men recently 2 pounds meat daily. The Germans give more food in the first three months of a sea cruise, thus very properly supplying a common craving among the younger men. These services also arrange their dietaries according to station, at home or abroad, the climate, the zones and seasons of the year. In public services it is not considered the part of a government to supply every requisite of luxury common to an elaborate dietary, but to subsist each individual safely and well, so that his capacities may be fully kept up.

The modern compact foods for troops, and composed of the essential nutrients in convenient shapes are now common in Europe, beginning with the famous pea sausage of the Germans in 1870–71. They are used in sudden rapid movements in sections of country bereft of food supplies; each man carrying his own supply for from three to four days, and a single wagon transports an infantry company's supply for a week. I present here a specimen recently made in Russia. It is made up in small oblong biscuits ¾ x 1½ inches, and the daily food allowance proposed in this form is of:

Iron Ration, Russian Army
Wheat cake, 200 grams.
Condensed vegs., 200 grams.
Burnt coffee, 25 grams.
Salt, 25 grams.

The tables following give in detail the U. S. Naval food supplies; the rations actually issued, at sea and in port, according to regulations. I have also added some selected standard dietaries, European and American, and specimen dietaries from several countries and our own, of people in many occupations, for comparisons. The data I have used for calculating the nutrient and dynamic values are mainly from the works of Prof. W. O. Atwater, (to whom I am under great obligations), Edward Smith, and Parkes, and I have endeavored to select those most in accord with the articles of the ration as familiar to me in a naval experience of twenty years. The results are, however, only approximative, and greater accuracy could be obtained by actual weighing of amounts eaten. In conclusion I would add that my views on the dieting of American seamen incline to the principles so ably advocated by Prof. Atwater, deduced from the experience of hundreds of dietaries in actual existence among our people; that is, less proportional carbohydrates, sugars and starches, and somewhat more fat than is usually given in the standards, and larger amounts of albuminates, the more easily assimilable stimulant food, and what is of much importance, the more satisfying. It is certainly true of American seamen, that they consume more protein relatively than seamen of other nationalities, and that they seem accordingly more active in labor and quicker witted.

Children and the World's Fair.—The Board of Lady Managers of the Columbian Exposition has undertaken to build and equip a structure devoted to children and their interests. Lectures will be given upon the development of the child's mental and moral nature by improved methods of home training. There will be a crèche for babies and a play-ground for children.

HERPETIC ERUPTIONS OF THE MOUTH AND PHARYNX IN CHILDREN.

Read in the Section of Diseases of Children, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY S. HENRY DESSAU, M.D.,
OF NEW YORK.

What is commonly known as a fever blister, or *herpes labialis*, has from the earliest days in medicine been associated in its causation with some disorder of the gastric function. There is every reason to believe that such is a fact, the immediate cause of the eruption being an irritation of a terminal nerve filament by a peculiar poison generated through some disorder of normal digestion by the fever process. For this reason herpes is now classed by dermatologists as a neurotic eruption. Now as herpes affects the lips, in some cases amongst children the eruption may also appear within the mouth, on the mucous membrane of the tongue, the pharynx and the tonsils. It will always be found that some degree of gastric disturbance, either with or without fever, has preceded the eruption in this locality.

Although there is nothing new offered in this statement, it is surprising that it is not more familiar to the profession. In a large practice amongst children extending over 20 years I have seen only a few *typical* cases of herpes of the mouth and pharynx. Here all doubt as to the correctness of the diagnosis was settled by the appearance of the vesicles upon the skin of the lower lip, and running back in almost a direct line, the eruption in the form of small apthous-like ulcers could be traced upon the mucous membrane of the lip, the gums, the dorsum and edge of the tongue and upon the tonsils. Without the characteristic eruption being demonstrated upon the skin of the lower lip, such cases might easily be mistaken for so-called aphthous or even follicular stomatitis. And this is the point that I desire to make in this short contribution. May we not rightly regard all of these affections of the mouth in children, excluding of course thrush, which is of parasitic origin, as herpetic, even though all of the typical features of the eruption be not present? Given a child whose nerve cells are sub-normal in point of nutrition, either from hereditary transmission or improper pabulum, and such child, other things being equal, will be far more liable than another child of a higher order of nerve organization, to the action of certain products of abnormal digestion, acting as a poison upon the nerve cells. These poisons I think may be identified as the ptomaines which are the product of fermentation caused by the presence of germs growing upon the albuminoids of the food and anatomical tissues.

Now in a young child whose nerve cells are decidedly more sensitive to disturbances of nutrition than at an older age, the slightest departure from the normal in physiological function will often be the means of producing an impression upon the cells controlling the terminal nerve filament. This peculiar predisposition to irritating influences may be witnessed in adults where local contact of certain substances, such as pepper, shell-fish or even saliva from kissing will produce herpes of the lip.

I have for some years entertained the opinion that the affection so commonly seen in children, known as follicular tonsillitis or *angina lacunaris*, is due to gastric disturbance, either from improper food or over-feeding. This view is strengthened by the result of treatment, which is a confirmation of the old aphorism, that "the cure shows the disease." My *treatment for this affection is entirely internal*, the difficulty of making local applications in young children being thus avoided. I *give calomel in doses of* $\frac{1}{16}$ grain in the form of the palatable tablet triturate, repeated every 2 or 3 hours for 2 or 3 days, and the successful result is prompt.

There is a great danger however, in a careless observer making a mistake in diagnosis in this affection, especially in view of the fact that there is a strong resemblence in the appearance of the parts in follicular tonsillitis to mild cases of diphtheria. In fact there is a determined disposition on the part of some authorities in pediatrics to call all affections of the pharynx, where there is the appearance of an exudation, diphtheria. Such a course would undoubtedly be safest on the whole, for the welfare of the general community, but at the same time our advance in the knowledge of medicine would be receiving a serious set-back. I think ordinary care in observation will overcome any danger of likelihood in spreading such a serious contagious disease as diphtheria. The exudation in mild forms of diphtheria, however slight it may be, is always uniform and consistent, even though it may not be extensive enough to be deeply embedded in the mucous membrane; while the exudation that covers the follicles in follicular tonsillitis, apthous stomatitis and typical herpes of the pharynx is pultaceous, breaking down easily when the parts are cleansed with a dossil of cotton wool. I am now referring only to the difference in the *appearance* of the exudations. I have referred to follicular tonsillitis at such length for the reason that I am inclined to place this affection as well as apthous and follicular stomatitis in the class of herpetic affections. They are in my opinion due to a similar original etiological factor as herpes, and in this regard I am pleased to find myself concurring with the views of Dr. Forcheimer as expressed in his article on "Apthous Stomatitis" in the May number of the *Archives of Pediatrics*. No better treatment in these affections of the mouth and pharynx in children can be found, than fractional doses of *calomel* given in the dose and form I have before mentioned. In such doses calomel acts as an undoubted stimulant of the liver, one of the five functions of which organ it is to destroy the poisons formed in the process of both normal and abnormal digestion of food and so prevent their entrance into the general circulation of the blood.

ADDRESS OF THE CHAIRMAN—PROGRESS AND NEEDS OF DENTISTRY.

Delivered before the Section of Oral and Dental Surgery, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich. June, 1892.

BY J. TAFT, M.D.,
OF CINCINNATI, O.

A backward glance for a year or two upon what has been accomplished affords ground for encouragement.

While, as is the case in almost every department of human occupation, there is a dark and a bright side, aspects discouraging and encouraging, yet it is quite apparent to the unbiased and faithful observer, that the dark side is becoming diminished in extent and lessened in intensity, and the bright is extending in all directions and assuming an increasing brightness. Discouragements are fading and encouragements growing.

I will for a brief time endeavor to direct attention to a few things that seem to afford warrant for this statement. If we look to the mere practical matters of our profession it is quite apparent that never before was there such an intense interest and earnestness shown as at the present time; never were practical methods, processes, instruments, appliances and materials examined, criticised and tested as to-day. It is no longer sufficient for a few to pass judgment in respect to any of these things, with the expectation that such decision will be accepted without question or challenge. While it is true that now more than ever before dentists are willing and even anxious to witness illustrations and demonstrations, it is equally true that every one, especially of the more progressive sort, must verify by his own tests and experience, that which he has witnessed at the hands of others; and as higher attainments have been made in the knowledge of underlying principles, these tests and examinations are more and more exacting and severe, thus bringing the greater probabilities of approximation to the truth.

There is a growing community of interest in all that pertains to the principles and practice of dentistry, in as much as almost the entire profession have given liberally of that which they possess, however it may have come to them.

There is a feeling of intolerance in the profession towards those who hold or retain from others anything new or valuable that may by any means have come into their possession. This principle is clearly presented in the Code of Ethics.

The opinions and views entertained in regard to the education and training of those who are to constitute the dentists of the future are undergoing rapid and radical changes, more pronounced than ever before. The enquiry comes from the pen or lips of every interested one—what can be done to avoid the errors and deficiencies of the past, and to make more thorough, complete and successful, the educational efforts that are now in operation, as well as those that may in the future be inaugurated?

Such questionings are indicative of an earnest desire for something better. As a result of these questionings and desires a very pronounced and significant change is now taking place in the educational schemes and methods suggested, and are being tested.

The old regular didactic lecture method, supplemented by vague and unsystematic clinical demonstrations, are no longer accepted and regarded as properly meeting the requirements. While the power of the lecturer—the living speaker, is esteemed as not less valuable than in the past—indeed it was never used with greater power and efficiency than at the present time—yet there have been brought into operation with it far better, more systematic, extended and thorough clinical demonstrations, and this not only to the observation of the learner, but he is subjected to the most thorough personal, manual training.

In connection with the lecture method, quizzing, reciprocal questioning, recitation, frequent writing upon the subjects of the course, and essays upon subjects assigned, together with class discussions, are being utilized to the great advantage of the learners.

No educational institutions, especially those of more than an elementary character, can assume to be well equipped for their work without a good library and museum. The library should contain, as fully as possible, the entire literature of all subjects and branches taught in any given institution.

Dental colleges should by no means be an exception in this respect. It is gratifying to know that the dental colleges of the country are turning attention to this important subject. Within the last two years more attention has been given to this question than ever before. Museums and appliances for illustrative teaching are commanding more attention and being more and more utilized. The number of dental schools has been much increased within the last two years, and most of these have established high requirements. It is a fact of great significance that the larger proportion of dental colleges recently organized have been in connection with medical colleges or universities; and some of the older dental colleges have sought and obtained alliances with universities. It is a noteworthy fact that in most cases of such alliance, the suggestion has originated with the medical schools, or with the authorities of universities. This fact considered in connection with another, viz.: that the first dental college ever organized sought an humble position with an established medical college, and was not only denied, but rudely repulsed, and with the statement made that the thought of such an alliance could not for one moment be entertained.

The favor with which dental colleges are now received by medical and other institutions is prophetic of great things for the future; it is an appreciation of dentistry by the medical profession that is not properly esteemed by the majority of dentists. Physicians have come to recognize dentistry as a department of the great healing profession, and that for the proper performance of its duties and responsibilities the groundwork of general medicine should be possessed by the dentists.

The increase in the number of dental schools is questioned, and even severely criticised by some; but that there is a surplus of thoroughly efficient schools will hardly be affirmed by any. Quite a number of the schools now in operation should raise their standard of requirements and teaching, or others should be established that would conform to the requirements of the times.

A great and important step was taken at the beginning of the current scholastic year, in the extension of the time required for graduation from two to three terms of not less than five months each. This was done in compliance with resolutions passed by the National Association of Dental Faculties, as follows:

Resolved, "That attendance upon three full regular courses of not less than five months each, in separate years, shall be required before examination for graduation."

It was further resolved:

"That we agree to adopt a graded course of instruction and an intermediate examination between each course, which course of instruction and examination shall be conducted as the faculties of the different colleges represented in this Association may deem proper."

This Association has been and is one of the most potent factors in promoting and maintaining the progress and welfare of the profession. Its influence is uplifting and is in a good degree effective in securing advanced methods of work and harmonious co-operation. During the last two years there has been a larger attendance at the dental colleges of the country than ever before, influenced somewhat, no doubt, by the more extended and strict requirements which came in force October 1, 1891.

A regular systematic course of college instruction and training is now recognized as the only proper method of entering the practice of the profession, and the recent legal enactments regulating the practice of dentistry have been formed with this idea prominently in view. No one who has not had such preparation will be acceptable in the more cultivated and refined communities. In the principal dental societies of the country graduation is a requisite for membership. This is a recognition of the desirability and value of thorough, systematic, scholastic professional training. This of course looks to a higher standard of professional attainments and excellence. There is in all our educational institutions a general disposition to extend the curriculum—the scheme of study and work. Branches that have from the beginning formed a part of the course are now more thoroughly and largely studied, and new subjects are being introduced from time to time, especially those that can be made tributary to the needs of a professional education.

Preliminary education now receives more attention than ever before. This subject received an impulse from the following action of the Association of Dental Faculties:

Resolved, That a preliminary examination be required for entrance to our dental colleges. Such requirements shall include a good English education. In case of any applicant failing to pass satisfactory preliminary examination, the other colleges of this Association shall be informed of the fact.

Resolved, That a candidate for matriculation who presents a diploma from a literary institution, or other satisfactory evidence of literary qualifications, shall be admitted without further examination.

Resolved, That we agree to adopt a graded course of instruction and an intermediate examination between each course, which course of instruction and examination shall be conducted as the faculties of the different colleges represented in this Association may deem proper.

Resolved, That after June, 1893, the yearly course of study shall not be less than seven months, two of which may be attendance upon clinical instruction in the infirmary of the school, now known as the intermediate or infirmary course.

This action of the Association was after due consideration passed by more than two-thirds of the members present, and now all the colleges (about thirty in number) represented in this Association conform to the requirements of these resolutions, which is regarded by all as a marked step in the line of progress.

Reference is often made to the rapid increase in the numbers entering our dental schools, and apprehension is expressed lest there should be an excess in the ranks of the profession—more than a supply for the demand. It is well for those who entertain such an idea to consider that this is, from this time onward, to be the only method of entering the practice of dentistry. The office pupilage road is about closed and will remain so. Again, those who graduate from our colleges do not all remain, but from ten to fifteen per cent., recognizing their want of natural ability or finding some more lucrative and inviting field of occupation, leave the practice of dentistry and enter a more (to them) acceptable service. Again, there are many in the profession who, though they have been in practice for many years, have fallen behind and are not able to cope with well equipped and thoroughly educated dentists of to-day. And they are constantly dropping out and leaving their fields to others better qualified. And as the public becomes more intelligent and better informed in regard to the value and importance of the teeth and learn that they are a necessity to the welfare and best interest of the animal economy, and understand fully the capability and resources of dental science and art, the demand will be made and must be answered for the best service possible. This growth in intelligence on the part of the people is fully keeping abreast with, if not outstripping, the boasted progress of dental skill and art. It is the bold assertion of one who has given much thought to the subject, that "There are not enough well equipped dentists in the United States to properly cleanse and keep clean the teeth of all the people of the country who need such service." This statement leaves out of view all other treatments and operations upon the teeth and mouth. Whether or not this statement is literally true as has been stated, we cannot affirm that there are more well equipped practitioners in our country than are needed; of the inferior variety there probably is an excess.

By reference to the graduations of the various dental colleges of the country for the year beginning June 1, 1891, and ending June 1, 1892, it is shown that from thirty of the leading colleges the degree of D.D.S. has been conferred upon 1,430, about ten per cent. of whom are foreigners and will go to other countries, thus leaving the number for this country 1,287. If ten per cent. of these drop out in a short time, it would leave as the net increase 1,160, which will hardly more than supply the decrease, and this leaves out of the estimate the increase in the country's population. The number of matriculates during the last year in these thirty schools was 2,727, deducting from these the graduates leaves 1,397 from which to form the senior and junior classes of the coming year. This view of the subject, if correct, indicates to us clearly that there is not now, nor is there likely to be in the near future, an excess in the numbers of dental practitioners in this country. And this is without question true in regard to those who possess a thorough preparation. Of this class there probably never will be an excess —more than the public welfare requires.

The progress of any department for the future depends upon the free response to certain requisites. Some of these may here be mentioned.

First in regard to our dental schools. Notwithstanding the improvements and progress that have been made, much yet requires to be done. More thorough work should be required upon most of the ordinary branches of the curriculum. In the past the time has been altogether insufficient, and acknowledgedly so, for the proper accomplishment of the work required. To meet this necessity either longer terms or an additional number should be required. The student's work from the beginning to the end of his course should be continuous. It is a mistake that the student is permitted to follow his special study and work for from four to six months in the year and to remain idle, so far as this work is concerned, the balance of the year. He should be made to realize that it is for his interest in some way or other to follow his course of instruction, study and work continuously from the beginning until his graduation. The time required for the completion of a course will depend upon the extent of that course, the natural ability, industry and energy of the student. It was formerly supposed that two five months's courses were quite sufficient. This idea now, however, is scarcely entertained by any one; the more extended the course, the greater number of branches embraced, the longer time will be required for the completion of the work upon them. A thorough consideration of this branch of the subject is an important need of the times.

The preliminary qualification and preparation of those who propose to enter upon a course of instruction for dental practice is one of far greater import than is usually supposed. Heretofore the practice has been that almost any one, regardless of his natural or acquired attainments, has been allowed to enter upon a course of study and work preparatory for dental practice. The evils resulting from this course have been quite apparent. It is impossible to make proper preparation without a right beginning. For the right accomplishment of a dental course, a trained mind is a requisite, one accustomed to systematic thought and study and well equipped in the knowledge of the branches of a liberal education. In addition to this, there should be certain natural qualifications and fitness for the work proposed. Rarely does any one present himself for entrance to a college without consulting a practitioner and endeavoring, to learn something as to what will be required of him. In all such cases the practitioner should exercise due discrimination and refuse to recommend or advise the unfit to enter upon a course of study. The subject of giving advice to intending students should be thoroughly considered and advisedly exercised by every practitioner. A course of this kind would very much aid our colleges in determining whom to accept or reject. Most colleges now require of those who apply certificates,or testimonials in regard to character and good standing. This, however, is not enough. These certificates are given by good citizens in any walk of life, but it would be well if every student who applies for entrance to a college would bring a statement from a well qualified dentist, giving his views as to the fitness of the person to enter upon such a course. It would be well if all colleges made such a requirement. It would then become incumbent upon every intending student to consult a good dentist and obtain his advice in reference to his capability. In the preparation of those who are to enter the ranks of the profession in the future it is important that more attention be given than in the past to a broad, liberal education and culture. The great mass of those who in the years gone by have entered the profession have been limited in this respect. A breadth and depth of culture gives power and strength. It makes one better in his profession, gives him a better standing and influence with his fellows with whom he comes in contact and mingles. It would be better perhaps, as a rule, to require preparatory to entering upon a course of medicine or dental study a classical education, and the tendency evidently is in this direction. A course of not less than one year of private pupilage would be a good initiative for the student, under a well qualified, faithful teacher, but this is so rare that to make it a requirement would avail little or nothing. But the members of the profession, though they may not be able to take or give proper instruction to private pupils, can be of immense service in an advisory way. Indeed, the profession is quite as responsible for the character of the graduates sent out as the colleges themselves. A student when applying to a college may be masked and even remain masked during his course of instruction, so that the authorities of the institution may not know his real character at all; but this view is very seldom the case with the neighbors, friends and associates of the young man. They know him without his mask and they should see to it that at least the colleges are not imposed upon in this way.

We may not now criticise the past; its work has been done and cannot be recalled; it was accomplished under circumstances and with a light very different from our environments of to-day. Perhaps the best possible was then accomplished, but the demands of the present are of a higher order and far more exacting than hitherto.

In respect to our colleges permit a suggestion which if carried out would place all upon a higher and more independent plane. As colleges at first and for many years were organized, they were dependent for support wholly upon the fees of those who patronized them. The income then was regulated by the number of those in attendance; the larger the number the greater the income. By-and-by this came to be so fully recognized that a different arrangement was sought and has in some institutions been carried out, either by endowment of the schools or by some other provision for their support independent of the income from students. A full and complete connection by dental colleges with a university or with endowed medical colleges would seem to be about the only way of escape from this unfortunate condition. It is true that in the future dental colleges may be endowed as such. Nothing of the kind has as yet been attempted so far as I am aware. Endowments for dental colleges have been said to be the great present need for dental colleges. How shall it best be accomplished?

And now a thought or two in reference to this organization which so closely allies us to the general medical profession. The very fact of this Section is an evidence of encouraging progress. It gives to dentistry a position which it did not occupy before; it brings upon its members and upon the members of the dental profession an added responsibility; it brings its practitioners into closer alliance with the members of other departments of the healing fraternity. It is prophetic of progress for the future and is a stimulus to those who rightly appreciate this inclination to go forward and make higher and higher attainments, and to render themselves worthy of the high trust placed upon them.

An attempt to measure and estimate the condition and status and progress of dentistry as it stands to-day compared with the past might with entire propriety embrace both the art and science—the practical and theoretical—and not only this but the influences and forces that are operative in promoting its development and growth. In what is now proposed, little more than a brief reference will be made to the art side of the subject; the intent is to note more especially some of the forces that are now operative for the further upbuilding and establishment of that department of the healing and restoring art with which we are the more immediately connected.

PERSONAL EXPERIENCES IN EMPYEMA OF THE MAXILLARY SINUS.

Read in the Section of Oral and Dental Surgery, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY H. GRADLE, M.D.,

OF CHICAGO, ILL.

Suppuration of the antrum is a subject so much discussed of late that it would be unprofitable to present to you anything but personal experiences on mooted points. The diagnosis of this trouble is easy only in cases with pronounced symptoms, but in very many it is quite difficult to be certain of it. In cases coming under your observation as dentists the dental history is often a definite guide in the diagnosis. In empyema however, of nasal origin, considerable diagnostic difficulty may be experienced.

The only constant symptom is discharge from the nose. If this be one-sided there can be scarcely any doubt that it comes from one of the accessory cavities, but not necessarily from the antrum of Highmore. When disease involves both sides, however, this criterion fails. A fetid odor strongly suggests retention of pus in a sinus. The pus is probably always fetid if of dental origin, but not necessarily if the antrum has been infected from the nose. The quantity of the discharge varies in different instances and is no criterion. If the pus can be seen issuing from underneath the middle turbinated bone it must come from either the frontal or the maxillary sinus.

Pain in and around the cheek is common but not constant in acute cases, but infrequent in chronic instances. Tenderness over the inflamed antrum I have never seen.

I have not been able to rely for diagnostic purposes upon translumination of the bone by means of an electric lamp placed in the mouth. In order to use this method the room must be very dark or an opaque hood must be put over the heads of surgeon and patient. An American lamp which I used at first I found too weak, but I find that I cannot rely either upon an eight-candle power furnished by Hirschman, of Berlin. The transparency varies with the configuration of the maxilla, and pus, unless copious and thick, does not impede the light much more than bone tissue.

An absolute diagnosis can only be made by exploration. This is a very innocent procedure when made from the alveolar process. If the teeth are sound, however, and there is no room between them, a puncture can be made through the canine fossa. It is well to incise the mucous membrane where it is still firmly attached to the alveolar process and to separate it upward from the bone. For if the loose tissue under the cheek is irritated by the instruments great swelling is apt to occur. This is not dangerous but very annoying. A physician can use a conical hand-drill instead of the dental engine, as the bony wall is not thick. Even the stout needle of the aspirator suffices sometimes to force its way into the sinus. If aspiration through a glass tube attached to the canula does not reveal pus the sinus may be irrigated with sterile salt solution. As this flows from the nose into a basin the presence or absence of pus is at once determined.

It has been stated by Ziem, who has had a very large experience, that in some cases pus cannot be found at the time of the puncture, but will issue on the next day. This is not due to a new infection during the operation. I have once had the same experience in a case where preëxisting asthma was at once benefitted by operating upon the antrum. It depends probably on the existence of incomplete partitions in the sinus.

While empyema of the antrum may not be attended by any characteristic symptom sufficient for a diagnosis it may yet cause considerable disturbances. These may be neuralgic pains, headaches, nasal stuffiness and discharge and other consequences of nasal irritability, such as asthma and less commonly derangements of the eyes and ears.

It does not seem to be commonly known that antral disease of nasal origin may heal spontaneously. I have often seen instances of acute coryza in which pus was seen to issue from the nasal orifice of the antrum. And yet after a time all suppuration ceased, nor were there after the recovery any evidences of disease of the antrum. A more positive proof was obtained in a lady in whom I opened the antrum through the canine fossa last September. There was a great deal of pus of mawkish odor but not decomposed. On account of irregular attendance the opening closed after the lapse of a week at a time when all symptoms, as well as the result of the irrigation two days previously, indicated the continued formation of pus. She then refused another operation. However, as she still has nasal discharge and irritability (and ear disease) I punctured the same antrum again this May, but found no pus on thorough search.

A curious observation which I have made twice was the removal of symptoms after the irrigation of the antrum where the operation did not confirm the diagnosis but revealed absolutely no pus. Once it was discharged from the nose, in the other case ciliary irritation and neuralgia without ocular lesions

In regard to treatment, I can add but little differing from general experience. In cases dating back no longer than a few months the drainage of the pus is sufficient for a cure. By opening the antrum, irrigating it with an indifferent sterile fluid and blowing in boracic acid we can cure the recent cases in from two to six weeks. A much longer time is required for cases of long standing, sometimes more than one year. In such chronic instances the opening should be made large. The easiest operation is from the alveolar process, if any teeth have been or are to be extracted or if there be room between them. But as this route does not, as a rule reach the lowest part of the antrum, Kuester's operation through the canine fossa is often more satisfactory. In the latter case a drainage tube can be worn; in the alveolar operation this is superfluous and even an obturator adapted by the dentist to keep the fistula open is of questionable service. One possible reason for the tedious recovery of old chronic cases is the occasional hypertrophy of the mucous membrane lining the antrum amounting even to a polypoid condition. Through a sufficiently large opening, I have used a curette with decided subsequent improvement and with but little pain in two such instances. Antiseptics have seemed to me to be of no greater influence than irrigation with salt water when the pus is copious. As the secretion is diminishing it is doubtful whether irrigation is at all necessary. The pus formation is distinctly checked by blowing into the cavity boracic acid or other soluble powders of similar antiseptic properties. In the more tedious class of cases this can be entrusted to an intelligent patient.

Discussion.

Dr. M. H. Fletcher said that he had had but little experience in cases of this kind, but related the case of one of his patients whom he took to a specialist for operation. The operator attempted to make an opening into the antrum through the canine fossa with a chisel, and found it so difficult that the patient was exhausted before an entrance was effected, and had to return home for rest. Coming back another day to have the operation completed, entrance was effected with a drill. The specialist said there had been a very unusual thickness of the bone; and Dr. Fletcher wished to ask whether such trouble was often found.

Dr. Gradle said that while there were variations in the thickness of the bone, it was rarely that any serious trouble was found.

Dr. E. S. Talbot said he had seen a case similar to the one mentioned by Dr. Fletcher, where the dentist had drilled into the nasal cavity instead of into the antrum. In many cases the antrum does not extend forward to the canine fossa, and if it does it will not extend more than one fourth to one-half inch back of the third molar. The operator in the case of Dr. Fletcher may have pierced the bone anterior to the antrum into the nasal cavity. Then besides, the antrum is sometimes divided by septa of bone. He believes the better way is to drill into the lower part of the cavity. When this is done it is easy to wash out the cavity with antiseptics, as the drainage will be good and the trouble will be cured.

(*Discussion to be concluded.*)

SOCIETY PROCEEDINGS.

American Public Health Association.

(*Concluded from page 755.*)

Wednesday, November 30.

The second morning session convened at 9:30 o'clock, Dr. Formento presiding.

After prayer by Rev. A. J. Steelman, five more applications for membership were admitted, similar to those at yesterday morning's session. It was a noticeable fact that more American physicians were in attendance than at either of the day sessions held on Tuesday.

The amendment to the Constitution offered last year at the Kansas City meeting was so amended as to include in the membership physicians of the Republic of Mexico and Mexican States. The election of one member to the advisory council from each State in the United States, States of Mexico, and Dominion of Canada, was then proceeded with, which is a very long list indeed.

The report of the treasurer, Dr. J. Berrien Lindsley, of Nashville, was then read, which summarized, is as follows:

Balance brought forward one year ago	$ 50 34
Annual dues	1,845 00
Sale of volumes	97 80
Total cash received	$1,993 14
DISBURSEMENTS.	
Printing and binding of Volume No. 17	$1,083 39
Office of Secretary for clerical help	250 00
Postage and clerical help for Treasurer	124 30
Expenses of Secretary for travelling	266 50
Expenses of Treasurer for travelling	111 59
	$1,835 78
Leaving a balance to new account of	$ 57 36

The first paper read was "The Sanitary Relations of Texas and Mexico," by Dr. R. M. Swearingen, of Austin, Texas. The author treated at considerable length the subject of quarantine. He stated that Texas is more open, and more exposed to small pox than any other State in the Union; that there were in his State last year 1,903 recorded cases of small pox. Of this number 464 had died. And $150,000 had been expended in caring for them.

During the present year thus far, there have been 1,109 cases with 300 deaths, and $19,341 had been expended caring for them, and Texas protests against these, impending evils.

The entire matter of his paper, which embraced the correspondence between himself, the Secretary of State, the Hon. James G. Blaine, the Governor of Texas, and Mexican Consuls at Vera Cruz, and elsewhere, was finally referred to this distinguished body (at this meeting) for a sanitary treaty.

(Discussion on the above subject was by vote deferred until Thursday.)

Dr. J. D. Plunket, of Nashville, offered the subjoined preamble and resolutions which, under the rules, was referred to the executive committee.

> "Whereas, The subject of hygiene is through the efforts of this organization now taught in the public schools of the U. S. A., at the University of Pennsylvania and Virginia, at Harvard, Yale, Bowdoin, and other colleges, and at the Naval Academy, at Annapolis, Md., and
>
> Whereas, Military hygiene as a branch of the general art of war, including the subjects of shelter, heating, ventilation, water supplies, food, disposal of sewage, and the clothing and physical training of troops, both in peace and in war should be recognized as a necessary and important part of the curriculum at all medical schools, and,
>
> Whereas, This important subject forms no part of the curriculum at the U. S. Military Academy at West Point, N. Y., therefore be it
>
> *Resolved*, That a committee of this Association be appointed to urge upon the Congress of the United States, the advisability of including the subjects of physiology and hygiene in the course of study at the Military Academy aforesaid.

The above were adopted on Friday afternoon, Dec. 2.

The second paper read was entitled "Defence of the Ports and Frontier Cities of Mexico against the Epidemic of Cholera that invaded Europe, and was on the point of invading the United States this year," by Dr. Eduardo Liceaga.

Third paper read was a short one entitled "A Modification of Inner Quarantine and Regulations as Especially applied to Epidemics of Yellow Fever," by Dr. D. B. Blake, of Curero, Texas.

Fourth paper, "On Yellow Fever, with some Considerations on Parasitism in Yellow Fever," by Dr. M. Carmona Y. Valle, of the City of Mexico. This paper elicited much applause.

Fifth paper read was a very brief one, entitled, "Discovery of a new Optical Combination for the Microscope," by Dr. Angel Gavino, City of Mexico.

Sixth paper, "Prophylaxis of Hydrophobia in Mexico," by Dr. Augustin Reyes (read in Spanish), City of Mexico. He spoke of having treated 659 cases with but three deaths or 0.45 per cent. Several ladies were present and listened to the proceedings with much interest.

The Association then adjourned until 3 P.M., at the Preparatory School.

The afternoon session convened at 3:30 o'clock at the appointed place, President Formento presiding.

In relation to the valuable paper read by Dr. Manuel Carmona, it was resolved to request the Supreme Board of Health of Mexico, to inquire into the reasons for the prevalence of yellow fever on the Atlantic coast while it has not appeared on the Pacific seaboard (as it was stated) but twice during the past century.

The first paper of this session was read by Dr. Juan Ramirez de Avellano, on "Croup in the City of Mexico, and Prophylactic Measures Against its Growth." It was read in his native tongue and proved to be a lengthy treatise upon this malady.

The succeeding paper was read by Mr. Mark W. Harrington Chief of the Weather Bureau at Washington D. C., on the "Relations of the Official Weather Service to Sanitary Science." The suggestions of the author were valuable and he closed his discussion amidst plaudits.

It was here suggested that the signal service officers of the United States and Mexico, be asked for data with a view of its application to sanitation, and that a committee be appointed with Mr. Harrington as Chairman. He consented to serve on such committee but thought a physician should be its chairman. Dr. Henry B. Baker, of Michigan, was then named, after which a motion prevailed that such committee be appointed.

The next paper read was upon "Typhoid Fever," by Dr. Nicholas Ramirez de Avellano which was discussed at considerable length by several Mexican physicians.

"Malarious Localities, How they may be made Salubrious," was the theme of an able essay by Dr. Charles Smart, Surgeon U. S. Army. He closed his paper amidst the applause of all present.

The Association then adjourned to meet at 3 P.M., Thursday at the Preparatory school.

Thursday Afternoon Session, December 1.

There was but one session of the Health Congress, Thursday, and that was held in the afternoon of that day, the morning having been occupied by the delegates in witnessing the inauguration of President Diaz and attending the public reception at the National Palace.

The Congress convened in the afternoon at 4 o'clock, an hour after the hour set: consequently the reading of several valuable papers had to be omitted.

Several unimportant announcements were made by the local committee of arrangements.

The executive and other committees reported.

There was a lengthy and exhaustive discussion of the quarantine question.

"Prophylactic against Ophthalmia in New-born Children," by Dr. Augustin Chacon, of the Federal District, was the first paper read and many new suggestions were made for the prevention of this frequent malady.

The next paper was by Henry F. Hoyt, M.D., Commissioner of Health, of St. Paul, Minn., and treated on "The Collection, Removal and Disposal of Garbage and Dead Animals at St. Paul." The matter was thoroughly discussed after Dr. Hoyt closed.

"Endemic and Epidemic Diseases as Observed in the Gulf Ports of Mexico'" was read by Dr. Luis E. Rulz, of this city, after which the congress adjourned until 9 A.M., Friday.

Friday, December 2.

This morning at 9:45 o'clock was begun the fourth or last day of the proceedings of this annual meeting with Dr. Formento in the chair.

After prayer by one of the resident ministers, several announcements by the Chairman of the Local Committee of Arrangements were made.

The executive committee reported 19 additional applications passed on, which took the usual course for election making 570 in all that had been elected members at this meeting.

Dr. Plunket's resolution offered on Wednesday was also recommended by the executive committee and as such was adopted.

Among the other resolutions adopted was that offered by Dr. Liceago, looking to the appointment of an International Commission of seven members from this body with Dr. Formento as Chairman to inquire into and adopt the most efficacious measures as to the best methods of preventing the spread of yellow fever, and the best means of quarantine from entering the ports of the U. S.

Also a resolution offered by Dr. Durgin of Boston, regarding the impending fear of cholera in the United States in

1892-93 petitioning Congress to so amend the emigration laws so as to provide for greater protection to our country from cholera (and he might have added other contagious and infectious diseases) and the prevention of importation of these diseases by having baggage properly fumigated. Also the following offered by Dr. A. L. Gihon after a long and desultory debate, in which several amendments were offered, and in succession they were tabled.

Resolutions offered and adopted by Medical Director Albert Gihon, U. S. N.

Resolved, That in view of the impending danger from cholera in 1893, it is the opinion of the American Public Health Association, that a National Health service should be established in the United States of America, as has been done in the Republic of Mexico, to procure uniformity of action in protecting the sea-coast from invasion by epidemic disease and to permit international sanitary conference and concert with this object, and that this Association respectfully requests the Congress of the United States to consider the imperative necessity for the prompt establishment of such a service, in the interest as well of the United States as of Canada and Mexico.

Resolved, That the Committee on National Health Legislation should be empowered and directed to communicate to this end with such committee as may be appointed by the Senate and House of Representatives of the United States to consider this matter.

Resolved, That the Committee on National Health Legislation shall be continued and enlarged to the number of thirteen.

Dr. Walcott of Boston, Chairman of the Committee on Legislation, submitted a lengthy report looking to the appointment of a National Health Bureau, or National Commissioner of Health by Congress, as a cabinet officer or chief sanitary officer of the U. S., and that the control of maritime quarantine should be in the hands of the National Government, which was adopted unanimously.

Dr. Griffin, Health Commissioner of Brooklyn, N. Y., offered the following preamble and resolutions which explain themselves; the same being referred to the Executive Committee; but for reasons best known to it, the committee did not report recommending their adoption.

WHEREAS, The American Public Health Association, at its meeting held in the City of Mexico, November 29, 30, and December 1 and 2, 1892, for the purpose of discussing matters relating to the public health and the best manner of preventing disease, and

WHEREAS, This country has been seriously menaced by an invasion of Asiatic cholera during the past summer and fall, particularly during that period between August 31 and October 21, 1892, when nine hundred and ninety-seven vessels from foreign ports, carrying eighty thousand and seventy-seven persons, passed through the quarantine of the port of New York, all having been personally examined by Dr. Wm. T. Jenkins, the Health Officer of the port of New York, and his assistants, and

WHEREAS, Through the vigilance, energy, zeal and efficiency of the investigations made by these officials, 266 cases of Asiatic cholera were discovered to have occurred on vessels coming from infected ports, and of this number ninety-six terminated fatally, seventy-six at sea and twenty at the quarantine (cholera) hospital Swinburne Island, and twenty-four deaths on board vessels in the port of New York, but in no instance was there a case of Asiatic cholera among any of this large number of persons that passed through quarantine. Therefore be it

Resolved, That this Association avails itself of this occasion, to express its high appreciation of the successful efforts of Dr. Wm. T. Jenkins, Health Officer of the port of New York, in preventing the introduction of Asiatic cholera.

Dr. Benjamin Lee, of Philadelphia, introduced a resolution, "That the Supreme Board of Health of Mexico be
requested to furnish the Association ng
virulent fevers peculiar to and most 1 "
which was also referred to the executi
ing to

per, entitled "Contributions

logical Study of the Drinking Waters of the City of Mexic
was read by Dr. José Ramirez, Secretary of the Supren
Board of Health, City of Mexico.

The above was discussed by Dr. Ojaros and Dr. Gavino.

The last paper of the afternoon session was read by I
Manuel Septien, of Queretaro, whose paper was one of tl
most interesting of the congress, and was entitled: "Impo
tance of Hygiene, and Convenience of Creating a Sanita
Department." During his discourse he said:

"The people and government of the United States ha
enthusiastically embraced the idea. That great natic
hardly born yesterday, and that to-day astonishes the wor
with its surprising development, that is unprecedented c
the earth, owes its wonderful prosperity to the practic
character of its sons and to the wise legislation th
governs it. Notwithstanding its rooted republican instinc
and strong adhesion to State rights, it acknowledges tl
necessity of submitting to a central authority that repr
senting the sanitary interests of the whole country, wi
unify and direct its course in the most convenient manner

At the conclusion he remarked:

"Gentlemen of the Hygiene Association, you who hav
consecrated yourselves to the noble study of the means c
prolonging life, you who form a part of this flourishing Asso
ciation and who have come to our country as missionarie
of peace and progress: Welcome to you all! May you
stay amongst us be a pleasant and profitable one; and whe
you return to your homes with our most fervent wishes fo
your continuous greatness, be assured that we also shal
continue our labors in the noble task of conquering for ma
the best happiness he can enjoy in this world."

The congress adjourned to meet at the Preparatory
School at 3 P.M.

AFTERNOON SESSION.

The afternoon session of the congress opened at 3:45 o'clock, vice-president Orvananos in the chair.

The election of officers was immediately proceeded with. Following is the report submitted to the Advisory Council, which was adopted:

President, Dr. S. H. Durgin, of Boston, Mass.

First Vice-President, Dr. Edua nga, of Mexico.

Second Vice-President, Dr. E Lachapelle, Mon-
treal, Canada.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES. . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
NO. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, DECEMBER 31, 1892.

A MEDICO-LEGAL PROBLEM.

A physician well educated and doing a large business in a country village, was thrown out of his carriage by a collision with a runaway team, and sustained a brain concussion. He was an invalid for a year suffering from general exhaustion and neuralgia. then resumed business as before. Some time later he became possessed with the idea that a merchant who owned the runaway team, had purposely and with design, started them running down the street, with the object of colliding and killing him. The merchant was a warm friend, and had left town on some business a short time before the accident occured, and this delusion was without the slightest basis in reason or fact. This delusion soon grew into a homicidal impulse, and the next year he made two ineffectual efforts to take the life of this merchant. The physician was arrested and bound over to keep the peace, and from that time a settled conviction pervades his mind that this merchant was in league with the devil; also that the entire community would suffer in many ways until this man was removed by death. To a few intimate friends he betrayed the most cunning malicious schemes, to assassinate and poison this man, and reasoned that it was his solemn duty to do so. He construes every act of this merchant to have a concealed purpose of injury to the community and himself.

This man is in active practice and gives no evidence of mental failure or trouble. He is cheerful, active and healthy. He never talks of this merchant, and will take pains to avoid if possible meeting him. These delusions are only mentioned to his intimate friends, and all efforts and reasoning to show their absurdity only fixes them more permanently in his mind. It is almost an absolute certainty, that a homicide will follow; its occurrence is a mere question of time and circumstances.

The practical inquiry is, what can be done? No medical examination would bring out any evidence of delusion and insanity. If this delusion was inquired into he would laugh it off, and deny that it was anything but a joke. His character, conduct and mental integrity would be above all suspicion. He conducts a large practice, and appears to possess excellent judgment, acting with discretion and without prejudice in all general matters. To his few intimate friends he displays the most startling evidence of the growth of this insane impulse, and cunning plans to carry it out. He was persuaded to go on a long vacation with his wife and some friends, and yet his mind was occupied, with schemes to carry out this impulse. An effort was made to break up this impulse, by a frank interview and free explanations, the merchant being aware of the purpose.

Apparently this delusion was broken up, and a complete reconciliation followed, yet in reality it was only strengthened. The practical step to have one or the other move away was found very difficult. The problem in the case was this, viz: a paranoiac and delusional mania, with concealed homicide impulse, to kill a certain man, is permitted to go in and out unrestricted, watching for an opportunity to carry out this impulse. There are no practical measures which can prevent this act. Crime will follow, then his real condition will be brought out in the evidence. This is not a single isolated case without parellel, but only one of a class, that unfortunately are becoming more prominent every year. In the efforts made to restrain these men, cunning lawyers for the defense have overwhelmed the medical testimony with confusion, and imputed the worst motives to physicians who were not able to make their testimony conform with the false legal standards. The theories on which the sanity of GUITEAU was decided, have been a sad blot on the progress of medical jurisprudence, along this line of study. The law is over half a century behind the medical recognition of these paranoiac cases.

Practical physicians in every community recognize the insanity of these concealed cases, and the criminal impulses which are certain to materialize into acts, but the law is powerless to help, and public opinion, opposes all application of restriction of liberty as insane, except where the symptoms are beyond all possible question to the minds of the laity. A great change must take place in this direction.

Disease and crime are more thoroughly preventable than curable by legal means. The great army of *mental defects*, whose crimes are symptoms, and signal flags of brain disease and distress, will come under medical care; then the practical solution of the great problems of to-day will be assured. To physicians the subject is an intensely material one, above all law opinion or theory, and the problem of

1892–93 petitioning Congress to so amend the emigration laws so as to provide for greater protection to our country from cholera (and he might have added other contagious and infectious diseases) and the prevention of importation of these diseases by having baggage properly fumigated. Also the following offered by Dr. A. L. Gihon after a long and desultory debate, in which several amendments were offered, and in succession they were tabled.

Resolutions offered and adopted by Medical Director Albert Gihon, U. S. N.

Resolved. That in view of the impending danger from cholera in 1893, it is the opinion of the American Public Health Association, that a National Health service should be established in the United States of America, as has been done in the Republic of Mexico, to procure uniformity of action in protecting the sea-coast from invasion by epidemic disease and to permit international sanitary conference and concert with this object, and that this Association respectfully requests the Congress of the United States to consider the imperative necessity for the prompt establishment of such a service, in the interest as well of the United States as of Canada and Mexico.

Resolved, That the Committee on National Health Legislation should be empowered and directed to communicate to this end with such committee as may be appointed by the Senate and House of Representatives of the United States to consider this matter.

Resolved, That the Committee on National Health Legislation shall be continued and enlarged to the number of thirteen.

Dr. Walcott of Boston, Chairman of the Committee on Legislation, submitted a lengthy report looking to the appointment of a National Health Bureau, or National Commissioner of Health by Congress, as a cabinet officer or chief sanitary officer of the U. S., and that the control of maritime quarantine should be in the hands of the National Government, which was adopted unanimously.

Dr. Griffin, Health Commissioner of Brooklyn, N. Y., offered the following preamble and resolutions which explain themselves; the same being referred to the Executive Committee; but for reasons best known to it, the committee did not report recommending their adoption.

Whereas, The American Public Health Association, at its meeting held in the City of Mexico, November 29, 30, and December 1 and 2, 1892, for the purpose of discussing matters relating to the public health and the best manner of preventing disease, and

Whereas, This country has been seriously menaced by an invasion of Asiatic cholera during the past summer and fall, particularly during that period between August 31 and October 21, 1892, when nine hundred and ninety-seven vessels from foreign ports, carrying eighty thousand and seventy-seven persons, passed through the quarantine of the port of New York, all having been personally examined by Dr. Wm. T. Jenkins, the Health Officer of the port of New York, and his assistants, and

Whereas, Through the vigilance, energy, zeal and efficiency of the investigations made by these officials, 266 cases of Asiatic cholera were discovered to have occurred on vessels coming from infected ports, and of this number ninety-six terminated fatally, seventy-six at sea and twenty at the quarantine (cholera) hospital Swinburne Island, and twenty-four deaths on board vessels in the port of New York, but in no instance was there a case of Asiatic cholera among any of this large number of persons that passed through quarantine. Therefore be it

Resolved. That this Association avails itself of this occasion, to express its high appreciation of the successful efforts of Dr. Wm. T. Jenkins, Health Officer of the port of New York, in preventing the introduction of Asiatic cholera.

Dr. Benjamin Lee, of Philadelphia, introduced a resolution, "That the Supreme Board of Health of Mexico be requested to furnish the Association statistics regarding virulent fevers peculiar to and most prevalent in Mexico," which was also referred to the executive committee according to rules.

The first paper, entitled "Contributions to the Bacteriological Study of the Drinking Waters of the City of Mexico," was read by Dr. José Ramirez, Secretary of the Supreme Board of Health, City of Mexico.

The above was discussed by Dr. Ojaros and Dr. Gavino.

The last paper of the afternoon session was read by Dr. Manuel Septien, of Queretaro, whose paper was one of the most interesting of the congress, and was entitled: "Importance of Hygiene, and Convenience of Creating a Sanitary Department." During his discourse he said:

"The people and government of the United States have enthusiastically embraced the idea. That great nation hardly born yesterday, and that to-day astonishes the world with its surprising development, that is unprecedented on the earth, owes its wonderful prosperity to the practical character of its sons and to the wise legislation that governs it. Notwithstanding its rooted republican instincts and strong adhesion to State rights, it acknowledges the necessity of submitting to a central authority that representing the sanitary interests of the whole country, will unify and direct its course in the most convenient manner."

At the conclusion he remarked:

"Gentlemen of the Hygiene Association, you who have consecrated yourselves to the noble study of the means of prolonging life, you who form a part of this flourishing Association and who have come to our country as missionaries of peace and progress: Welcome to you all! May your stay amongst us be a pleasant and profitable one; and when you return to your homes with our most fervent wishes for your continuous greatness, be assured that we also shall continue our labors in the noble task of conquering for man the best happiness he can enjoy in this world."

The congress adjourned to meet at the Preparatory School at 3 P.M.

Afternoon Session.

The afternoon session of the congress opened at 3:45 o'clock, vice-president Orvananos in the chair.

The election of officers was immediately proceeded with. Following is the report submitted to the Advisory Council, which was adopted:

President, Dr. S. H. Durgin, of Boston, Mass.

First Vice-President, Dr. Eduardo Liceaga, of Mexico.

Second Vice-President, Dr. Emanuel P. Lachapelle, Montreal, Canada.

Secretary, Dr. Irving A. Watson, Concord, N. H.

Treasurer, Dr. Henry D. Holton, Brattleboro, Vermont.

Three new members of Executive Committee: Drs. Wm. Bailey, of Louisville, Ky., Henry F. Hoyt, of St. Paul, Minn., and Mr. Robt. F. Gayol, of Mexico.

Papers were then read by Drs. Adolfo Castanares, Geo. Homan, José M. Benitez and Jesus Chico. A large number of papers remain over referred to the committee on publication.

During the meeting the invariably expressed opinion was that the utmost vigilance should be observed to prevent an entrance of cholera in this country next summer. An important committee was appointed to go before congress for the purpose of having the laws of emigration so amended to prevent an outbreak of this scourge in this country next year, and the one way to do this was to have the immigration of steerage passengers stopped during the greater part of 1893. The Dominion of Canada and the Republic of Mexico will cooperate with the United States in this matter.

Of the large number present at the meeting, about 148 members attended from the United States, many of whom were accompanied by ladies, bringing the list of "visitors" well-nigh to 300.

The Association adjourned on Friday at 5:15 P.M., December 2, to convene at Chicago, during the month of October, 1893.

Apparently this delusion was broken up, and a complete reconciliation followed, yet in reality it was only strengthened. The practical step to have one or the other move away was found very difficult. The problem in the case was this, viz: a paranoiac and delusional mania, with concealed homicide impulse, to kill a certain man, is permitted to go in and out unrestricted, watching for an opportunity to carry out this impulse. There are no practical measures which can prevent this act. Crime will follow, then his real condition will be brought out in the evidence. This is not a single isolated case without parellel, but only one of a class, that unfortunately are becoming more prominent every year. In the efforts made to restrain these men, cunning lawyers for the defense have overwhelmed the medical testimony with confusion, and imputed the worst motives to physicians who were not able to make their testimony conform with the false legal standards. The theories on which the sanity of GUITEAU was decided, have been a sad blot on the progress of medical jurisprudence, along this line of study. The law is over half a century behind the medical recognition of these paranoiac cases.

Practical physicians in every community recognize the insanity of these concealed cases, and the criminal impulses which are certain to materialize into acts, but the law is powerless to help, and public opinion, opposes all application of restriction of liberty as insane, except where the symptoms are beyond all possible question to the minds of the laity. A great change must take place in this direction.

Disease and crime are more thoroughly preventable than curable by legal means. The great army of mental defects, whose crimes are symptoms, and signal flags of brain disease and distress, will come under medical care; then the practical solution of the great problems of to-day will be assured. To physicians the subject is an intensely material one, above all law opinion or theory, and the problem of

1892–93 petitioning Congress to so amend the emigration laws so as to provide for greater protection to our country from cholera (and he might have added other contagious and infectious diseases) and the prevention of importation of these diseases by having baggage properly fumigated. Also the following offered by Dr. A. L. Gihon after a long and desultory debate, in which several amendments were offered, and in succession they were tabled.

Resolutions offered and adopted by Medical Director Albert Gihon, U. S. N.

Resolved, That in view of the impending danger from cholera in 1893, it is the opinion of the American Public Health Association, that a National Health service should be established in the United States of America, as has been done in the Republic of Mexico, to procure uniformity of action in protecting the sea-coast from invasion by epidemic disease and to permit international sanitary conference and concert with this object, and that this Association respectfully requests the Congress of the United States to consider the imperative necessity for the prompt establishment of such a service, in the interest as well of the United States as of Canada and Mexico.

Resolved, That the Committee on National Health Legislation should be empowered and directed to communicate to this end with such committee as may be appointed by the Senate and House of Representatives of the United States to consider this matter.

Resolved, That the Committee on National Health Legislation shall be continued and enlarged to the number of thirteen.

Dr. Walcott of Boston, Chairman of the Committee on Legislation, submitted a lengthy report looking to the appointment of a National Health Bureau, or National Commissioner of Health by Congress, as a cabinet officer or chief sanitary officer of the U. S., and that the control of maritime quarantine should be in the hands of the National Government, which was adopted unanimously.

Dr. Griffin, Health Commissioner of Brooklyn, N. Y., offered the following preamble and resolutions which explain themselves; the same being referred to the Executive Committee; but for reasons best known to it, the committee did not report recommending their adoption.

WHEREAS, The American Public Health Association, at its meeting held in the City of Mexico, November 29, 30, and December 1 and 2, 1892, for the purpose of discussing matters relating to the public health and the best manner of preventing disease, and

WHEREAS, This country has been seriously menaced by an invasion of Asiatic cholera during the past summer and fall, particularly during that period between August 31 and October 21, 1892, when nine hundred and ninety-seven vessels from foreign ports, carrying eighty thousand and seventy-seven persons, passed through the quarantine of the port of New York, all having been personally examined by Dr. Wm. T. Jenkins, the Health Officer of the port of New York, and his assistants, and

WHEREAS, Through the vigilance, energy, zeal and efficiency of the investigations made by these officials, 266 cases of Asiatic cholera were discovered to have occurred on vessels coming from infected ports, and of this number ninety-six terminated fatally, seventy-six at sea and twenty at the quarantine (cholera) hospital Swinburne Island, and twenty-four deaths on board vessels in the port of New York, but in no instance was there a case of Asiatic cholera among any of this large number of persons that passed through quarantine. Therefore be it

Resolved, That this Association avails itself of this occasion, to express its high appreciation of the successful efforts of Dr. Wm. T. Jenkins, Health Officer of the port of New York, in preventing the introduction of Asiatic cholera.

Dr. Benjamin Lee, of Philadelphia, introduced a resolution, "That the Supreme Board of Health of Mexico be requested to furnish the Association statistics regarding virulent fevers peculiar to and most prevalent in Mexico," which was also referred to the executive committee according to rules.

h first paper, entitled "Contributions to the Bacteriological Study of the Drinking Waters of the City of Mexico," was read by Dr. José Ramirez, Secretary of the Supreme Board of Health, City of Mexico.

The above was discussed by Dr. Ojaros and Dr. Gavino.

The last paper of the afternoon session was read by Dr. Manuel Septien, of Queretaro, whose paper was one of the most interesting of the congress, and was entitled: "Importance of Hygiene, and Convenience of Creating a Sanitary Department." During his discourse he said:

"The people and government of the United States have enthusiastically embraced the idea. That great nation hardly born yesterday, and that to-day astonishes the world with its surprising development, that is unprecedented on the earth, owes its wonderful prosperity to the practical character of its sons and to the wise legislation that governs it. Notwithstanding its rooted republican instincts and strong adhesion to State rights, it acknowledges the necessity of submitting to a central authority that representing the sanitary interests of the whole country, will unify and direct its course in the most convenient manner."

At the conclusion he remarked:

"Gentlemen of the Hygiene Association, you who have consecrated yourselves to the noble study of the means of prolonging life, you who form a part of this flourishing Association and who have come to our country as missionaries of peace and progress: Welcome to you all! May your stay amongst us be a pleasant and profitable one; and when you return to your homes with our most fervent wishes for your continuous greatness, be assured that we also shall continue our labors in the noble task of conquering for man the best happiness he can enjoy in this world."

The congress adjourned to meet at the Preparatory School at 3 P.M.

AFTERNOON SESSION.

The afternoon session of the congress opened at 3:45 o'clock, vice-president Orvananos in the chair.

The election of officers was immediately proceeded with. Following is the report submitted to the Advisory Council, which was adopted:

President, Dr. S. H. Durgin, of Boston, Mass.

First Vice-President, Dr. Eduardo Liceaga, of Mexico.

Second Vice-President, Dr. Emanuel P. Lachapelle, Montreal, Canada.

Secretary, Dr. Irving A. Watson, Concord, N. H.

Treasurer, Dr. Henry D. Holton, Brattleboro, Vermont.

Three new members of Executive Committee: Drs. Wm. Bailey, of Louisville, Ky., Henry F. Hoyt, of St. Paul, Minn., and Mr. Robt. F. Gayol, of Mexico.

Papers were then read by Drs. Adolfo Castanares, Geo. Homan, José M. Benitez and Jesus Chico. A large number of papers remain over referred to the committee on publication.

During the meeting the invariably expressed opinion was that the utmost vigilance should be observed to prevent an entrance of cholera in this country next summer. An important committee was appointed to go before congress for the purpose of having the laws of emigration so amended to prevent an outbreak of this scourge in this country next year, and the one way to do this was to have the immigration of steerage passengers stopped during the greater part of 1893. The Dominion of Canada and the Republic of Mexico will coöperate with the United States in this matter.

Of the large number present at the meeting, about 148 members attended from the United States, many of whom were accompanied by ladies, bringing the list of "visitors" well-nigh to 300.

The Association adjourned on Friday at 5:15 P.M., December 2, to convene at Chicago, during the month of October, 1893.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES. . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.
[illegible]uld send their Annual Dues to the
[illegible] D., Lock Box 1271, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1271, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, DECEMBER 31, 1892.

A MEDICO-LEGAL PROBLEM.

A physician well educated and doing a large business in a country village, was thrown out of his carriage by a collision with a runaway team, and sustained a brain concussion. He was an invalid for a year suffering from general exhaustion and neuralgia. then resumed business as before. Some time later he became possessed with the idea that a merchant who owned the runaway team, had purposely and with design, started them running down the street, with the object of colliding and killing him. The merchant was a warm friend, and had left town on some business a short time before the accident occured, and this delusion was without the slightest basis in reason or fact. This delusion soon grew into a homicidal impulse, and the next year he made two ineffectual efforts to take the life of this merchant. The physician was arrested and bound over to keep the peace, and from that time a settled conviction pervades his mind that this merchant was in league with the devil; also that the entire community would suffer in many ways until this man was removed by death. To a few intimate friends he betrayed the most cunning malicious schemes, to assassinate and poison this man, and reasoned that it was his solemn duty to do so. He construes every act of this merchant to have a concealed purpose of injury to the community and himself.

This man is in active practice and gives no evidence of mental failure or trouble. He is cheerful, active and healthy. He never talks of this merchant, and will take pains to avoid if possible meeting him. These delusions are only mentioned to his intimate friends, and all efforts and reasoning to show their absurdity only fixes them more permanently in his mind. It is almost an absolute certainty, that a homicide will follow; its occurrence is a mere question of time and circumstances.

The practical inquiry is, what can be done? No medical examination would bring out any evidence of delusion and insanity. If this delusion was inquired into he would laugh it off, and deny that it was anything but a joke. His character, conduct and mental integrity would be above all suspicion. He conducts a large practice, and appears to possess excellent judgment, acting with discretion and without prejudice in all general matters. To his few intimate friends he displays the most startling evidence of the growth of this insane impulse, and cunning plans to carry it out. He was persuaded to go on a long vacation with his wife and some friends, and yet his mind was occupied with schemes to carry out this impulse. An effort was made to break up this impulse, by a frank interview and free explanations, the merchant being aware of the purpose.

Apparently this delusion was broken up, and a complete reconciliation followed, yet in reality it was only strengthened. The practical step to have one or the other move away was found very difficult. The problem in the case was this, viz: a paranoiac and delusional mania, with concealed homicide impulse, to kill a certain man, is permitted to go in and out unrestricted, watching for an opportunity to carry out this impulse. There are no practical measures which can prevent this act. Crime will follow, then his real condition will be brought out in the evidence. This is not a single isolated case without parellel, but only one of a class, that unfortunately are becoming more prominent every year. In the efforts made to restrain these men, cunning lawyers for the defense have overwhelmed the medical testimony with confusion, and imputed the worst motives to physicians who were not able to make their testimony conform with the false legal standards. The theories on which the sanity of GUITEAU was decided, have been a sad blot on the progress of medical jurisprudence, along this line of study. The law is over half a century behind the medical recognition of these paranoiac cases.

Practical physicians in every community recognize the insanity of these concealed cases, and the criminal impulses which are certain to materialize into acts, but the law is powerless to help, and public opinion, opposes all application of restriction of liberty as insane, except where the symptoms are beyond all possible question to the minds of the laity. A great change must take place in this direction.

Disease and crime are more thoroughly preventable than curable by legal means. The great army of mental defects, whose crimes are symptoms, and signal flags of brain disease and distress, will come under medical care; then the practical solution of the great problems of to-day will be assured. To physicians the subject is an intensely material one, above all law opinion or theory, and the problem of these paranoiacs is simply cause and effect along the line of physiological and psychological law.

RIGHT OF STATES TO REGULATE THE PRACTICE OF MEDICINE AND SURGERY.

The legislature of Oregon has enacted a law, under which every practitioner of medicine and surgery is required to obtain a certificate from the State Board of Examiners that he is a graduate of a medical institution in good standing, to entitle him to practice his profession; or, if he is not a graduate, that he has been found, upon examination by the board, to be qualified to practice medicine or surgery; or that he was a practitioner of medicine or surgery, and was so engaged at the passage of the act; and the law also provides that any person practicing medicine or surgery without obtaining such certificate shall be deemed guilty of a misdemeanor, and punishable by a fine or imprisonment or both, in the discretion of court.

This law was attacked upon the ground that it was unconstitutional (1) because it discriminates between the citizens of Oregon by permitting one to practice medicine or surgery who was so engaged when the law took effect, without examination, while it denies the privilege to another, who may wish to engage in the practice after the passage of the act; and (2) because it discriminates between residents and non-residents of the State, by permitting a physician who was a resident and engaged in the practice when the act took effect to continue the pursuit of his profession without examination, while it denies the privilege to a non-resident, who may seek to engage in the practice, unless he undergoes an examination by the board, or is a graduate and in possession of a diploma.

The first point was based on the assumption that this law is in conflict with the State constitution, which provides that "no law shall be passed granting to any citizens or class of citizens privileges or immunities which, upon the same terms, shall not equally belong to all citizens;" and the second point was based on a like assumption, that the law is in conflict with the constitution of the United States, which provides that "the citizens of each State shall be entitled to all privileges and immunities of citizens in the several States;" and also in conflict with that portion of the fourteenth amendment thereto which provides that "no State shall make or enforce any law which shall abridge the privileges or immunities of the citizens of the United States."

Neither of these contentions is tenable, says the Supreme Court of Oregon, in deciding the case referred to, State *v.* Randolph. The right of every person to pursue any lawful business, occupation or profession he may choose to pursue, subject to such restrictions as the government may impose for the protection of the health, welfare and safety of society, is unquestioned. This paramount right, inherent in every government, to provide such regulations in regard to various avocations as the public welfare may require is very broad and comprehensive. It has been said: That all laws for the protection of the lives, limbs, health and quiet of persons, and the security of all property within the State, fall within this general power of the government, and that under the general police power of the State, persons and property are subjected to all kinds of restraints and burdens in order to secure the general comfort, health and prosperity of the State; of the perfect right in the legislature to do which no question ever was, or, upon acknowledged general principles, ever can be made, so far as natural persons are concerned. Whatever difficulty, therefore, there may be in defining the precise limits and boundaries by which the exercise of this power may be governed, all agree that laws and regulations necessary for the protection of the health, morals and safety of society are strictly within the legitimate exercise of the police power.

Among the various occupations of life, there are many which may be pursued by a person without danger to the public health or detriment to the public welfare, and need, therefore, no regulations to control them; but there are other occupations or callings which require special knowledge or training or experience to qualify a person to pursue them with safety to the public health and interests; and when the occupation or calling is of this character no one can question the power of the State to impose such restrictions and to provide such regulations as it may deem proper for the protection of the health and welfare of its citizens from the evils resulting from ignorance and incapacity. "The power of the State," said MR. JUSTICE FIELD, "to provide for the general welfare of its people, authorizes it to prescribe all such regulations as, in its judgment, will secure or tend to secure them against the consequences of ignorance and incapacity, as well as of deception and fraud." There are few professions that require more careful preparation to qualify a person to practice than medicine; and certainly there are few that more nearly concern the comfort, health and life of every citizen. In view of the important interests committed to the charge of the physician, the necessity that he should possess the necessary qualifications of learning and skill is so great, and his want of them likely to be attended with results so injurious to health and destructive of life, that the power of the State to enact such laws regulating the practice of medicine and surgery as are calculated to exclude and protect the people from ignorant pretenders and charlatans has been established by repeated adjudications, and is now too firmly settled to admit of doubt. For the accomplishment of this purpose—that is, to provide means for the protection of the public health from the ignorance and incapacity of those who are unfitted to discharge the duties of a physician—Oregon, as other States have done, enacted the law in question, and, unless it grants to some citizen or physician, or class of them, some right or immunity which, upon like terms, or under similar circumstances, it denies to another, it is a valid exercise of police power, and must be upheld.

As it is the right of the State to prescribe qualifications based on knowledge or professional skill, necessarily the State must be the judge of such qualifications, and, if the rule established to determine them is reasonable and appropriate for that purpose, it cannot operate to deprive any one of the privilege or right to practice his profession. The test of qualification, under the act, is based on medical skill and knowledge. If the person seeking to practice medicine has a diploma or license from some reputable institution, it is sufficient evidence, under the act, of the requisite qualifications to entitle him to practice. It is only when the person wishing to practice has no such evidence of his qualification that the act requires that he shall submit himself for examination by the board. In establishing this rule, the State saw fit, for reasons satisfactory to itself, to except from its provisions those physicians who were engaged in the practice at the passage of the act. In doing this it made the fact of being so engaged in the practice at that time sufficient evidence of qualification—equivalent to a diploma—rendering an examition unnecessary. To apply the language of Chief Justice Hawley, of Nevada, it in effect declared that the physician or surgeon who was engaged in the practice immediately preceding the passage of the act was as well qualified, in the judgment of the State, to continue the practice of his profession, as the student, coming fresh from the halls of college with his diploma, was to commence it. But in establishing this rule as to these physicians and surgeons the State did not deny the privilege or the right of practicing medicine and surgery to any one. No class of citizens of this State is prohibited from the practice of medicine or surgery by the act, provided they have the proper qualifications, and comply with the law in relation thereto. The error of the first contention consists in assuming that the act grants "privileges or immunities" to one class of citizens or physicians of this State which it denies to other citizens of the State or other States.

The act does not grant privileges or immunities to any citizen or class of citizens, either within or without the State. It only establishes a rule of evidence by which qualification to practice medicine and surgery is to be determined. It makes the fact of a person being engaged in the practice when the law took effect sufficient evidence of his fitness to continue the practice of his profession without an examination, in the same way that the diploma of the student is accepted as sufficient evidence of his fitness to commence the practice without an examination. Such and similar provisions regulating the practice of medicine do not operate to deprive any one of the privilege to practice his profession, and have uniformly been held by the courts to be constitutional.

THE ANTI-VIVISECTIONISTS OF LONDON.

Mr. Lawson Tait has taken public stand in the company of the opponents of vivisection. At an anniversary meeting held in October, he participated in the attacks then made upon the existing laws that govern the medical experimentation on the lower animals. As reported, Mr. Tait subscribes to the opinion that no useful knowledge can now be obtained by the methods of modern laboratory research employed by all, or nearly all, of our leading physiologists and pathologists. Mr. Tait characterized these methods as mediæval and compared them with "pressing an accused person with weights in order to make him plead." He pronounced the defenders of vivisection to be without logical argument. These positions of Mr. Tait are not exactly new, for there have already been made counter-attacks upon him; for example, Mr. Horsley has said of him in public that while Mr. Tait is admittedly an operating surgeon of great dexterity, his writings show him to be ignorant of science and her requirements; and that he seldom loses an opportunity of declaring his contempt for pathological science, "to do which is to place himself out of touch with the modern school of thought." Mr. Tait invites such compliments as these and he probably heeds them not. The great lights of the London profession, Sir James Paget, Sir Andrew Clark, Sir William Jenner, and Dr. Wilks are among the defenders of vivisection and have publicly reprobated the acts of the anti-party. The late Sir William Gull was, during his lifetime, in the same company of thinkers: he was on one occasion asked by a lady if he did not regard the experimentation on the lower animals, as done by the men of medical research, as an act of unnecessary cruelty. "Madame," he replied, "there is no cruelty comparable to ignorance." Sir William Jenner has pointed out the strange inconsistencies of the opponents of medical vivisection when those persons call for no restrictions in the commercial or agricultural attacks on predatory animal life. As he said in 1876, any man may catch a rat in the most cruelly devised kind of trap, hunt it with dogs, or poison it with strychnine, or destroy it as he pleases, from motives of fear, dislike, or for the preservation of property, but when a scientist puts himself in a position to cause pain, however slight, with a view of increasing knowledge and the relief of human suffering, he finds himself the subject of repressive legislation, and is even branded as a malefactor by the fanatical members of the opposing party.

DOMESTIC CORRESPONDENCE.

Revision of the Code of Ethics.

To the Editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

"A Conservative Member" opposes the revision of the Code of Ethics of the Association in THE JOURNAL of Dec. 10, for six reasons. In the first four I find the following specifications "its phraseology is lucid;" "it does not contain any superfluous statements;" "the words are simple, the language is pure and good and the presentation of the subject is clear and logical;" "all its provisions are distinctly stated, and it does not contain any expressions that can be justly condemned or that require modification."

Probably the writer was one of the original members of the Association and is wedded to the redundant phraseology of the period when the Code was written. Has he read the editorial of the "*Medical News*," of Sept. 17? If so, will he give your readers the benefit of his opinion of the views therein contained bearing on the quotations above made from his letter? INQUIRER.

SELECTIONS.

CHLOASMA UTERINUM.—Chloasma is simply, so far as its ocular appearance is concerned, an abnormal deposit of pigment in the skin without interfering with the character or function of it.

The term chloasma in its general sense indicates only a condition without even suggesting a probable exciting cause for the pigmentation. It may be due to direct mechanical irritation of long standing; it may be due to some organic disease, as consumption, scrofula, etc.; it may be due to nervous irritability or dependent upon some change or irritation in the uterine organs.

Concerning this last named condition, *which might be* termed uterine chloasma, I desire to say a word, because it is the most common form and most amenable to treatment.

It is rare that we see this disease begin and develop before puberty or after the menopause. Its existence is dependent upon the abnormal activity of the generative organs. From observation I am led to believe that excessive venery is one of the more common sources of irritation that produce the deposit of pigment. In all those cases in which I have been permitted to make a vaginal and uterine examination there was a flabby and enlarged uterus, the cavity of which, including the cervix, measured from three and a half to five inches. The uterine walls also were more or less thickened, and both the os externum and internum somewhat dilated; in short, the uterus assumes *the condition* and appearance of subinvolution as is occasionally seen following confinement. But this condition exists not alone in females who have been pregnant, but in females as well where conception has never taken place.

Uterine chloasma runs an indefinite course; it may exist even to old age or gradually fade away, as it often does, in proportion as the generative organs lose their irritability beginning with the menopause. Since the patches may exist a long time even after uterine irritation has subsided, we are led to infer that the nervous system furnishes in part *that condition on which the deposit of pigment depends*, else there would be no return of it after its removal.

The diagnosis in a general way is not difficult; the most perplexing portion is to differentiate the various causes that may produce such a condition and discover the active one. As before stated, uterine enlargement has been found in every case where a full examination has been permitted; the inference is therefore drawn, right or wrong, that in every case of uterine chloasma there is, in a greater or less degree, an enlargement of the uterus, but the enlargement and irritability of it may depend upon some neurosis.

Our treatment therefore must be twofold: First, to *remove the discoloration of the skin*; and second, to restore the parts on which the discoloration depends to their normal condition. It would be almost useless to attempt to *remove the discoloration without first removing its cause*; both may be treated together, however, advantageously. For the former condition the most satisfaction has been derived from the use of bichloride of mercury (not gold), five grains to the ounce of water, carefully painted over the affected skin. In a few days a bran-like desquamation will appear and with it more or less of the deposit of pigment. After exfoliation of the superficial layers of the epidermis, if pigment still exists, the process may be repeated and continued as long as pigmentation remains.

For the latter condition medicines administered by the mouth are of doubtful utility; personally I have been unable to observe any benefit arising from the administration of any drug by the mouth or subcutaneously. The only treatment that has been of avail consisted of direct applications to the uterus, stimulating it to activity and causing in it powerful contractions; for this electricity may be used, especially galvanism, which causes tonic muscular contractions. But what has served my purpose better is the insertion into the uterus of a soluble intra-uterine pencil which by its presence causes powerful contractive pains resembling labor pains, and thus causes a reduction in size of the organ in a mechanical way. A repetition of this process will in due time restore the organ to its natural condition. This pencil can be most easily inserted by use of a "pencil carrier," procurable of any good instrument maker. One may be improvised, if need be, from an ordinary catheter. Any pencil may be used containing any drug that suits the fancy of the prescriber; preferably I prescribe a pencil containing iodoform on account of *its antiseptic properties. But uterine* contraction in such cases is produced by local irritation, hence it matters but little what the composition of the pencil may be, unless other conditions exist in and about the uterus which must be taken into account. I believe—a belief founded upon past experience—that a judicious treatment along the lines indicated will serve to eliminate that unsightly condition known as uterine chloasma.—A. A. Young, M.D., in *New York Medical Journal.*

MISCELLANY.

OFFICIAL LIST OF CHANGES in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from December 17, 1892, to December 23, 1892.

Capt. W. B. Banister, Asst. Surgeon U. S. A., is hereby granted leave of absence for fifteen days, to take effect on or about January 11, 1893.

Capt. Peter R. Egan, Asst. Surgeon U. S. A., is granted leave of absence for four months, with permission to go beyond sea.

Capt. James D. Glennan, Asst. Surgeon U. S. A., leave of absence granted is extended thirteen days.
